## Edetate Calcium Disodium

**AHFS 64:00**

### Products

Edetate calcium disodium is available in 5-mL ampuls containing 200 mg/mL of the drug in water for injection.<sup>3237</sup> For intravenous infusion, the appropriate dose of edetate calcium disodium should be added to 250 to 500 mL of dextrose 5% or sodium chloride 0.9%, or the drug should be diluted to a concentration of approximately 0.5% (5 mg/mL) or less in one of these solutions.<sup>3237 3238</sup>

### Trade Name(s)

Calcium Disodium Versenate

### Administration

After establishment of adequate urine flow with intravenous fluid administration prior to the first dose, edetate calcium disodium may be administered intravenously or intramuscularly.<sup>3237 3238</sup> The manufacturer states that intravenous and intramuscular routes of administration have been found to be equally effective.<sup>3237</sup> Because of the pain associated with intramuscular injection, continuous intravenous infusion generally is preferred; however, the intramuscular route is used in all patients with overt lead encephalopathy and is preferred in patients with lead encephalopathy and cerebral edema.<sup>3237 3238</sup> The intramuscular route also is preferred by some for use in

young pediatric patients<sup>3237</sup> or may be considered when fluid restriction is required.<sup>3238</sup>

For intravenous infusion, the appropriate dose of the drug should be added to 250 to 500 mL of dextrose 5% or sodium chloride 0.9% and infused over 8 to 12 hours.<sup>3237</sup> The drug also has been diluted to a concentration of approximately 0.5% (5 mg/mL) or less in dextrose 5% or sodium chloride 0.9% and administered as a continuous infusion over 24 hours.<sup>3238</sup> When the intravenous route of administration is used, rapid infusion should be avoided.<sup>3237</sup>

The total daily dose may be given by intramuscular injection in equally divided doses at 8- to 12-hour intervals.<sup>3237</sup> To minimize pain at the injection site, the drug should be mixed in equal volumes with lidocaine hydrochloride 1% or procaine hydrochloride 1% injection (no longer commercially available in the US) (e.g., 1 mL of local anesthetic for each mL of edetate calcium disodium injection) or 0.25 mL of lidocaine hydrochloride 10% injection can be added to 5 mL of edetate calcium disodium injection to yield a final local anesthetic concentration of 0.5%.<sup>3237 3238</sup>

### Stability

Edetate calcium disodium in intact ampuls should be stored at controlled room temperature.<sup>3237</sup>

## Edrophonium Chloride

AHFS 36:56

### Products

Edrophonium chloride is available in 15-mL multiple-dose vials.<sup>3227</sup> Each mL of solution contains edrophonium chloride 10 mg with phenol 0.45% and sodium sulfite 0.2%; the solution also contains sodium citrate and citric acid as buffers.<sup>3227</sup>

### pH

Approximately 5.4.<sup>3227</sup>

### Trade Name(s)

Enlon

### Administration

Edrophonium chloride is administered intravenously.<sup>3227</sup> The drug also may be administered intramuscularly in adults with inaccessible veins or in pediatric patients, owing to the difficulty of intravenous injection in pediatric patients.<sup>3227</sup> The drug also has been administered subcutaneously in infants.<sup>3228</sup>

### Stability

Intact vials should be stored at controlled room temperature.<sup>3227</sup>

## Enalaprilat

AHFS 24:32.04

### Products

Enalaprilat is available in 1- and 2-mL vials.<sup>3249</sup> Each mL of solution contains enalaprilat 1.25 mg with sodium chloride to adjust tonicity and benzyl alcohol 9 mg in water for injection.<sup>3249</sup> The solution also may contain sodium hydroxide to adjust the pH.<sup>3249</sup>

### Administration

Enalaprilat is administered intravenously slowly over at least 5 minutes either undiluted or diluted with up to 50 mL of a compatible intravenous infusion solution.<sup>3249</sup>

### Stability

Enalaprilat is a clear, colorless solution.<sup>3249</sup> Intact vials should be stored at controlled room temperature.<sup>3249</sup>

Enalaprilat solution should be visually inspected for particulate matter and discoloration prior to administration.<sup>3249</sup>

### Central Venous Catheter

Enalaprilat (Merck) 0.1 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Enoxaparin Sodium

AHFS 20:12.04.16

### Products

Enoxaparin sodium is available as a solution with each mL containing 100 or 150 mg of the drug in water for injection.<sup>3351</sup> The 100-mg/mL concentration is available in both preservative-free, single-dose, prefilled syringes, containing 30 mg/0.3 mL and 40 mg/0.4 mL, and preservative-free, single-dose, graduated prefilled syringes, containing 60 mg/0.6 mL, 80 mg/0.8 mL, and 100 mg/1 mL.<sup>3351</sup> The 100-mg/mL concentration also is available in 3-mL multidose vials preserved with benzyl alcohol 15 mg/mL.<sup>3351</sup> The 150-mg/mL concentration is available in preservative-free, single-dose, graduated prefilled syringes, containing 120 mg/0.8 mL and 150 mg/1 mL.<sup>3351</sup>

### pH

From 5.5 to 7.5.<sup>3351</sup>

### Units

The approximate anti-factor Xa activity is 1000 international units for every 10 mg of enoxaparin sodium.<sup>3351</sup>

### Trade Name(s)

Lovenox

### Administration

Enoxaparin sodium is administered by deep subcutaneous injection, without dilution, alternating administration sites between the left and right anterolateral and left and right posterolateral abdominal wall.<sup>3351</sup> To avoid loss of drug when administering the 30- and 40-mg prefilled syringes, the air bubble from the syringe should *not* be expelled prior to injection of the drug.<sup>3351</sup> To minimize bruising, the injection site should not be rubbed after completion of the injection.<sup>3351</sup>

Enoxaparin sodium solution in multidose vials is administered by intravenous bolus injection into an intravenous line.<sup>3351</sup> The drug may be mixed with sodium chloride 0.9% or dextrose 5%.<sup>3351</sup> The line used to administer enoxaparin sodium should be flushed with a sufficient volume of dextrose or sodium chloride prior to and following intravenous bolus injection of enoxaparin sodium.<sup>3351</sup> The manufacturer states that enoxaparin sodium should not be mixed or co-administered with other drugs.<sup>3351</sup>

Enoxaparin sodium is not intended for intramuscular administration and must not be administered by this route.<sup>3351</sup>

### Stability

Enoxaparin sodium injection is a clear, colorless to pale yellow solution.<sup>3351</sup> Intact containers should be stored at controlled room temperature.<sup>3351</sup> Enoxaparin sodium solutions should be visually inspected for particulate matter and discoloration prior to administration.<sup>3351</sup> One manufacturer has noted that degradation in the color of enoxaparin is a known phenomenon

and that such color changes outside of product specifications have been observed at increased temperatures (e.g., 40°C) over periods of 3 to greater than 6 months; however, the manufacturer states that this color degradation does not affect the potency of the drug.<sup>3356</sup>

One manufacturer of enoxaparin sodium (Sanofi) has stated that prefilled graduated syringes containing 60 mg/0.6 mL and 100 mg/1 mL were stable for 12 months at 4°C, 25°C with 60% relative humidity, and 30°C with 60% relative humidity and that such syringes containing 30 mg/0.3 mL were stable for 36 months at 4°C.<sup>3356</sup> Enoxaparin sodium 100-mg/mL solution in 3-mL multidose vials was stable for 3 months at 25°C with 60% relative humidity, 30°C with 60% relative humidity, and 40°C with 75% relative humidity and for 24 months at 25°C with 60% relative humidity.<sup>3356</sup> The stability of the solution in the multidose vial was similar to that of the 100-mg/mL solution in prefilled syringes, and the presence of benzyl alcohol in the multidose vial did not affect stability.<sup>3356</sup>

Multidose vials should not be stored for more than 28 days after first use.<sup>3351</sup>

Enoxaparin sodium (Aventis) 100-mg/mL solution (as 60-mg/0.6 mL prefilled syringes) diluted to 20 mg/mL in sterile water for injection has been reported to undergo little or no change in anti-factor Xa activity for 29 days at 22 to 26°C when the dilution was packaged in glass vials.<sup>2499</sup>

Enoxaparin sodium (Aventis) 100-mg/mL solution diluted to 20 mg/mL with dextrose 4% and stored in glass vials had 0.7 and 2.8% losses of baseline anti-factor Xa activity when stored for 31 days at 4 and -12°C, respectively; solutions stored at -80°C had a 6.6% loss in 14 days.<sup>3352</sup>

### Temperature Effects

Solutions of enoxaparin sodium heated to 70°C exhibited a rapid decline in anti-factor Xa activity within 8 hours, with a maximum loss of 27%.<sup>3365</sup> Anti-factor Xa activity returned to 94% of initial activity after 12 hours, with a subsequent decline to 84% of initial anti-factor Xa activity after 48 hours and 80% after 22 days.<sup>3365</sup>

### Freezing Solutions

Freezing solutions of enoxaparin sodium at or below temperatures of -26°C resulted in substantial losses of anti-factor Xa activity, with greater losses associated with lower temperatures.<sup>3364</sup> Samples frozen at -12°C exhibited no loss, whereas samples frozen at -26 and -196°C exhibited losses of 14 and 67%, respectively.<sup>3364</sup> Losses of anti-factor Xa activity appeared to be independent of the duration of freezing time.<sup>3364</sup> Anti-factor Xa activity also decreased with increasing freeze-thaw cycles; only 13% of anti-factor Xa activity remained after 50 such cycles of freezing at -196°C and subsequent thawing at room temperature.<sup>3364</sup> Rapid freezing with subsequent slow thawing or slow

freezing with subsequent rapid thawing resulted in negligible losses in anti-factor Xa activity as compared with rapid freezing with subsequent rapid thawing.<sup>3364</sup>

### Syringes

Enoxaparin sodium (Rhône-Poulenc Rorer) 100-mg/mL solution (as 30-mg/0.3 mL prefilled syringes) was packaged in 1-mL tuberculin syringes (Monoject, Sherwood) fitted with 27-gauge, ½-inch needles.<sup>2272</sup> The syringes were stored at 22 and 3°C for 10 days.<sup>2272</sup> A 7 to 8% loss in anti-factor Xa activity occurred in 10 days under refrigeration at 3°C, but 15 to 25% losses occurred in as little as 2 days at 22°C.<sup>2272</sup>

One manufacturer of enoxaparin sodium (Sanofi) has indicated that the 100-mg/mL undiluted solution containing benzyl alcohol 15 mg/mL repackaged in 3 types of plastic syringes (tuberculin, Terumo; Safety-Lok, Becton Dickinson; Monoject, Sherwood) is stable for 5 days at room temperature.<sup>3355</sup> Because benzyl alcohol was not found to influence the stability of enoxaparin sodium 100-mg/mL solution,<sup>3355</sup> <sup>3356</sup> it has been proposed that a preservative-free solution of the same strength also would be stable in such plastic syringes.<sup>3355</sup>

Enoxaparin sodium (Aventis) 100-mg/mL solution (as 60-mg/0.6 mL prefilled syringes) diluted to 20 mg/mL in sterile water for injection packaged as 0.3 mL in 1-mL plastic tuberculin syringes has been reported to undergo little or no change in anti-factor Xa activity for about 14 days at 22 to 26°C and at 2 to 6°C.<sup>2499</sup>

The stability of enoxaparin sodium 100-mg/mL solution packaged in 1-mL polypropylene tuberculin syringes was evaluated over 10 days stored at 22 and 4°C. Enoxaparin losses did not exceed 10% at either storage temperature; however, 7 of 45 test syringes stored at room temperature could not be operated to eject the enoxaparin. None of the refrigerated samples exhibited this failure. The authors speculated that precipitation had resulted in blockage.<sup>2546</sup>

Enoxaparin sodium (Clexane, Sanofi Aventis) preservative-free 150-mg/mL solution diluted to 20 mg/mL with sodium chloride 0.9% and stored in polypropylene syringes retained at least 90% of baseline anti-factor Xa and anti-factor IIa activity when stored for up to 43 days at 22 to 26°C exposed to natural light and at 2 to 8°C in the dark; the anti-factor Xa activity of solutions stored at 22 to 26°C in the dark decreased to 89% by day 8, but exhibited anti-factor Xa activity greater than 90% at the next test (i.e., day 15) and throughout the remainder of the study (i.e., up to 43 days).<sup>3353</sup> Authors noted that some solutions exhibited a trend towards an increase in anti-factor Xa activity during this time period due to an unknown mechanism.<sup>3353</sup>

Enoxaparin sodium (Aventis) 100-mg/mL solution diluted with either dextrose 4% or sterile water for injection or undiluted was stored in 1-mL plastic tuberculin syringes at 4, -12, and -80°C for 31 days.<sup>3352</sup> Enoxaparin sodium diluted to 20 mg/mL with dextrose 4% had 0.6 and 2.2% losses of baseline anti-factor Xa activity when stored for 31 days at 4 and -12°C, respectively; solutions stored at -80°C had a 6.6% loss in 14 days.<sup>3352</sup> Enoxaparin sodium diluted to 20 mg/mL with sterile water for injection had a 6.3% loss in 14 days at 4°C and a 3% loss in 7 days at -12°C; solutions stored at -80°C had a loss of more than 10% in 7 days.<sup>3352</sup> Undiluted enoxaparin sodium 100-mg/mL solution had no loss at 4°C in 31 days, 4.9% loss at -12°C in 7 days, and more than 10% loss at -80°C in 7 days.<sup>3352</sup>

Enoxaparin sodium (Aventis) 100-mg/mL solution (as 40-mg/0.4 mL prefilled syringes) was diluted to 8 mg/mL with sterile water for injection and stored in polypropylene syringes (Becton Dickinson) at 2 to 6°C for 30 days.<sup>3354</sup> Solutions retained greater than 90% anti-factor Xa activity for 14 days; however, authors noted that there was a substantial amount of variability in anti-factor Xa activity due to an unknown mechanism.<sup>3354</sup>

## Ephedrine Sulfate

AHFS 12:12.12

### Products

Ephedrine sulfate is available as a concentrate for injection in single-dose 1-mL vials and ampuls.<sup>2754 3336 3337</sup> Each mL of the concentrate for injection contains ephedrine sulfate 50 mg in water for injection.<sup>2754 3336 3337</sup> The pH may have been adjusted with sodium hydroxide and/or glacial acetic acid, if necessary.<sup>2754 3337</sup>

The concentrate for injection must be diluted prior to intravenous administration.<sup>2754 3336 3337</sup> For bolus administration, 1 mL (50 mg) of ephedrine sulfate should be diluted in 9 mL of sodium chloride 0.9% or dextrose 5% to a final concentration of 5 mg/mL.<sup>2754 3336 3337</sup> An appropriate dose of the diluted solution of ephedrine sulfate should be withdrawn for administration.<sup>2754 3336 3337</sup>

### Equivalency

Ephedrine sulfate 50 mg is equivalent to 38 mg of ephedrine base.<sup>2754 3336 3337</sup>

### pH

From 4.5 to 7.<sup>2754 3336 3337</sup>

### Trade Name(s)

Akovaz, Corphedra

### Administration

Ephedrine sulfate concentrate for injection must be diluted prior to intravenous administration.<sup>2754 3336 3337</sup> The drug is administered as an intravenous bolus<sup>2754 3336 3337</sup> or infusion.<sup>3336</sup>

The drug also has been administered by subcutaneous or intramuscular injection,<sup>2314</sup> however, FDA-approved labeling does not include these routes.<sup>2754 3336 3337</sup>

### Stability

Intact ampuls and vials of ephedrine sulfate should be stored at controlled room temperature in their original cartons to protect from light.<sup>2754 3336 3337</sup> The drug should be visually inspected for particulate matter and discoloration prior to administration,<sup>2754 3336 3337</sup> if particulate matter is present or if discoloration or cloudiness occurs, the solution should not be used.<sup>3336 3337</sup> Ampuls and vials of ephedrine sulfate are intended for single use only, and any remaining drug should be discarded.<sup>2754 3336 3337</sup>

### Syringes

The stability of ephedrine (salt form unspecified) 10 mg/mL repackaged in polypropylene syringes was evaluated. Little or no change in concentration was found after 4 weeks of storage at room temperature not exposed to direct light.<sup>2164</sup>

Ephedrine sulfate (Ben Venue) 5 mg/mL in sodium chloride 0.9% was packaged in 10-mL polypropylene syringes (Becton Dickinson) and stored at 25°C in fluorescent light and at 4°C. Ephedrine sulfate losses were less than 3% after 60 days under both conditions.<sup>2365</sup>

Ephedrine sulfate 50 mg/mL packaged in polypropylene syringes (Becton Dickinson) was stable for 4 days at room temperature. Analysis found little or no loss of ephedrine sulfate, and no change in solution appearance occurred.<sup>2649</sup>

# Epinephrine Hydrochloride

AHFS 12:12.12

## Products

Epinephrine hydrochloride 1 mg/mL is available in 1-mL ampuls, 30-mL vials, and 0.3-mL auto-injector syringes. Epinephrine hydrochloride is also available at a concentration of 0.1 mg/mL (1:10,000) in vials and prefilled syringes. Some products also contain sodium chloride, a bisulfite antioxidant, and an antibacterial preservative such as chlorobutanol.<sup>1(11/05) 4</sup>

## pH

From 2.2 to 5.<sup>4 17</sup>

## Osmolality

The osmolality of epinephrine hydrochloride (Abbott) 0.1 mg/mL was determined to be 273 mOsm/kg by freezing-point depression.<sup>1071</sup> A 1-mg/mL solution was determined to have an osmolality of 348 mOsm/kg.<sup>1233</sup>

## Trade Name(s)

Adrenalin Chloride, Epipen

## Administration

Epinephrine hydrochloride may be administered by subcutaneous, intramuscular, intravenous, or intracardiac injection. Intramuscular injection into the buttocks should be avoided.<sup>1(11/05) 4</sup> Intravenous infusion at a rate of 1 to 10 mcg/min has also been described.<sup>4</sup>

## Stability

Epinephrine hydrochloride is sensitive to light and air.<sup>4 1259</sup> Protection from light is recommended. Withdrawal of doses from multiple-dose vials introduces air, which results in oxidation. As epinephrine oxidizes, it changes from colorless to pink, as adrenochrome forms, to brown, as melanin forms.<sup>4 1072</sup> Discolored solutions or solutions containing a precipitate should not be used.<sup>4</sup> The various epinephrine preparations have varying stabilities, depending on the form and the preservatives present. The manufacturer's recommendations should be followed with regard to storage.<sup>4</sup>

The stability of epinephrine hydrochloride in intact ampuls subjected to resterilization to provide a sterile outer surface was evaluated. Epinephrine hydrochloride (adrenalin injection, BP) ampuls were resterilized by the following methods:

1. Autoclaved at 121°C for 15 minutes.
2. Autoclaved at 115°C for 30 minutes.
3. Exposed to ethylene oxide–freon (12:88) at 55°C for 4 hours followed by aeration at 50°C for 12 hours.

No loss of epinephrine hydrochloride concentration was found in samples from any of these methods. However, if ampuls were resterilized by autoclaving 2 times at 121°C for 15 minutes, 8% of the drug was lost.<sup>803</sup>

Epinephrine hydrochloride is rapidly destroyed by alkalis or oxidizing agents including sodium bicarbonate, halogens, permanganates, chromates, nitrates, nitrites, and salts of easily reducible metals such as iron, copper, and zinc.<sup>4</sup>

Visual inspection for color changes may be inadequate to assess compatibility of epinephrine hydrochloride admixtures. In one evaluation with aminophylline stored at 25°C, a color change was not noted until 8 hours had elapsed. However, only 40% of the initial epinephrine hydrochloride was still present in the admixture at 24 hours.<sup>527</sup>

## pH Effects

The primary determinant of catecholamine stability in intravenous admixtures is the pH of the solution.<sup>527</sup> Epinephrine hydrochloride is unstable in dextrose 5% at a pH above 5.5.<sup>48</sup> The pH of optimum stability is 3 to 4.<sup>1072</sup> In one study, the decomposition rate increased twofold (from 5 to 10% in 200 days at 30°C) when the pH was increased from 2.5 to 4.5.<sup>1259</sup>

When lidocaine hydrochloride is mixed with epinephrine hydrochloride, the buffering capacity of the lidocaine hydrochloride may raise the pH of intravenous admixtures above 5.5, the maximum necessary for stability of epinephrine hydrochloride. The final pH is usually about 6. Epinephrine hydrochloride will begin to deteriorate within several hours. Therefore, admixtures should be used promptly after preparation or the separate administration of the epinephrine hydrochloride should be considered. This restriction does not apply to commercial lidocaine–epinephrine combinations that have had the pH adjusted for epinephrine stability.<sup>24</sup>

## Syringes

Epinephrine hydrochloride was diluted to 1 and 7 mg/10 mL with sterile water for injection and repackaged into 10-mL glass vials and plastic syringes with 18-gauge needles (Becton Dickinson). The diluted injections were stored at room temperature protected from light. Epinephrine stability was evaluated over 56 days of storage. The 1-mg/10-mL samples had an epinephrine loss of 4 to 6% in 7 days and 13% in 14 days. The 7-mg/10-mL samples lost 2% in the glass vials and 5% in the syringes in 56 days.<sup>1902</sup>

Epinephrine hydrochloride 1:10,000 in autoinjector syringes was evaluated for stability over 45 days under use conditions in paramedic vehicles. Temperatures fluctuated with locations and conditions and ranged from 6.5°C (43.7 °F) to 52°C (125.6 °F) in high desert conditions. No visually apparent changes occurred, and not more than 6% loss of epinephrine hydrochloride was found. Most samples exhibited no loss.<sup>2548</sup>

Epinephrine hydrochloride under simulated summer conditions in paramedic vehicles was exposed to temperatures ranging from 26 to 38°C over 4 weeks. Analysis found no loss of the drug under these conditions. However, the buffer in the injection was altered, resulting in an increase in pH.<sup>2562</sup>

### Central Venous Catheter

Epinephrine hydrochloride (American Regent) 0.1 mg/mL in dextrose 5% was found to be compatible with the ARROW-g+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of

the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

# Epirubicin Hydrochloride

**AHFS 10:00**

## Products

Epirubicin hydrochloride is available as a clear, red, preservative-free, ready-to-use 2-mg/mL solution in single-use 25- and 100-mL vials containing 50 and 200 mg of drug, respectively.<sup>3377</sup> The solution also contains sodium chloride and water for injection.<sup>3377</sup> The pH has been adjusted with hydrochloric acid.<sup>3377</sup>

## pH

Adjusted to 3.<sup>3377</sup>

## Trade Name(s)

Ellence

## Administration

Epirubicin hydrochloride is administered slowly by intravenous infusion into the tubing of a freely running intravenous infusion of sodium chloride 0.9% or dextrose 5%.<sup>3377</sup> The manufacturer states that initial therapy at the recommended starting dosage generally should be infused over 15 to 20 minutes.<sup>3377</sup> For patients receiving reduced dosages (e.g., due to organ dysfunction and/or dosage modification for toxicity), the infusion time may be proportionally decreased; however, the drug should not be infused over less than 3 minutes.<sup>3377</sup> Administration by direct push injection is not recommended because of the risk of extravasation.<sup>3377</sup>

Extravasation may occur even in the presence of adequate blood return upon needle aspiration.<sup>3377</sup> Extravasation may cause local pain, severe tissue lesions (e.g., vesication, severe cellulitis), and necrosis and should be avoided.<sup>3377</sup> Burning or stinging may indicate perivenous infiltration, which requires immediately terminating the infusion and restarting it in another vein.<sup>3377</sup> Perivenous infiltration also may occur without pain.<sup>3377</sup> Venous sclerosis may result from injection of the drug into a small vessel or from repeated injection into the same vein.<sup>3377</sup> Facial flushing and erythematous streaking along the vein may result from excessively rapid administration and may precede local phlebitis or thrombophlebitis.<sup>3377</sup> Decreasing the duration of infusion of the drug proportionally with an indicated dosage reduction is intended to reduce the risk of thrombosis or perivenous extravasation, which could in turn reduce the risk of severe cellulitis, vesication, or tissue necrosis.<sup>3377</sup> Infusion of the drug into veins occurring over joints or in extremities with compromised venous or lymphatic drainage should be avoided if possible.<sup>3377</sup> Epirubicin hydrochloride must *not* be administered by intramuscular or subcutaneous injection.<sup>3377</sup>

As with other toxic drugs, caution should be exercised in the handling and preparation of epirubicin hydrochloride.<sup>3377</sup> Personnel preparing and administering the drug should take protective measures to avoid contact with the solution, including use of disposable gloves, gowns, masks, and goggles.<sup>3377</sup> Dose

preparation preferably should be performed in a suitable laminar airflow device on a work surface protected by disposable, plastic-backed, absorbent paper.<sup>3377</sup> Procedures for the proper disposal of epirubicin hydrochloride should be considered; all equipment and materials used in the preparation and administration of doses and for cleaning should be disposed of safely in high-risk waste disposal bags intended for high-temperature incineration.<sup>3377</sup> In the event of spills or leaks, the manufacturer recommends preferably soaking first with a dilute sodium hypochlorite (1% available chlorine) solution, followed by water.<sup>3377</sup> Hands always should be washed after removing gloves.<sup>3377</sup> If accidental skin or eye contact with the drug occurs, the affected area(s) should be flushed immediately with a large amount of water, soap and water, or a sodium bicarbonate solution; the skin should not be abraded by using a scrub brush.<sup>3377</sup> Medical attention should be sought.<sup>3377</sup>

## Stability

Intact vials should be stored at 2 to 8°C and protected from freezing and exposure to light.<sup>3377</sup> Although vials should be stored under refrigeration, manufacturers note that refrigeration of epirubicin hydrochloride injection can result in the formation of a gelled product; however, the gelled product will return to a slightly viscous to mobile solution after 2 to 4 hours (maximum) at a controlled room temperature of 15 to 25°C.<sup>3377</sup> Epirubicin hydrochloride solution should be visually inspected for particulate matter and discoloration prior to administration.<sup>3377</sup> Vials are for single use only and any unused portion should be discarded.<sup>3377</sup> Manufacturers recommend that any unused solution from the single-dose vials be discarded within 24 hours after initial puncture of the vial stopper.<sup>3377</sup>

The manufacturer states that the drug should not be mixed with other drugs in the same syringe.<sup>3377</sup>

## pH Effects

Epirubicin hydrochloride stability is pH dependent. The drug becomes progressively more stable at acid pH, with maximum stability at pH 4 to 5.<sup>1007 1460</sup> Prolonged contact of epirubicin hydrochloride with any solution having an alkaline pH should be avoided because of the resulting hydrolysis of the drug.<sup>3377</sup>

## Light Effects

Although epirubicin hydrochloride is photosensitive, no special precautions are necessary to protect solutions containing epirubicin hydrochloride 500 mcg/mL or greater during intravenous administration,<sup>1463</sup> even over periods extending to 14 days in room light.<sup>2081</sup>

## Syringes

Epirubicin hydrochloride 2 mg/mL in sterile water for injection was stable for at least 43 days at 4°C in Plastipak (Becton Dickinson) plastic syringes.<sup>1460</sup>

Epirubicin hydrochloride 0.5 mg/mL in sodium chloride 0.9% was reported to be stable for at least 28 days at 4 and 20°C when stored in plastic syringes.<sup>1564</sup>

Epirubicin hydrochloride 2 mg/mL in sodium chloride 0.9% in 50-mL polypropylene syringes with blind luer hubs was stored at 25°C both in light and dark and at 4°C in dark. About 2 to 4% loss occurred in 14 days at 25°C whether in light or dark. No loss was found after 180 days of refrigerated storage.<sup>2081</sup>

Epirubicin hydrochloride (Farmorubicine, Pfizer) lyophilized powder formulation containing methylparaben and lactose was reconstituted with sodium chloride 0.9% to a final concentration of 8.33 mg/mL and stored as 6 mL in 50-mL brown polypropylene syringes (Becton Dickinson) with polypropylene caps protected from light.<sup>3378</sup> The solution was reported to be physically and chemically stable, retaining at least 95% of the initial

concentration for 72 hours at 4°C with or without additional storage for 4 hours at 22°C.<sup>3378</sup>

### Sorption

Although epirubicin hydrochloride was initially reported to undergo sorptive losses to PVC containers, subsequent studies have shown no loss to glass, PVC, and high-density polyethylene containers, PVC, polyethylene, and polybutadiene infusion sets, and polypropylene syringes.<sup>1460 1577 1700</sup>

### Filtration

Epirubicin hydrochloride 50 mg/1000 mL in dextrose 5% and sodium chloride 0.9% was infused over 24 hours and exhibited a drug loss during the initial period of filtration through cellulose ester and nylon filters; however, the concentrations returned to expected levels within minutes, and the total amount of drug lost was deemed negligible.<sup>1577</sup>

# Epoetin Alfa

## AHFS 20:16

### Products

Epoetin alfa is available in 1-mL single-use (unpreserved) vials containing 2000, 3000, 4000, and 10,000 units/mL. The solution also contains in each mL albumin human 2.5 mg, sodium citrate 5.8 mg, sodium chloride 5.8 mg, and citric acid 0.06 mg in water for injection.<sup>1(8/08)</sup>

Preservative-free single-dose epoetin alfa is also available in 1-mL vials containing 40,000 units along with albumin human 2.5 mg, sodium phosphate monobasic monohydrate 1.2 mg, sodium phosphate dibasic anhydrate 1.8 mg, sodium citrate 0.7 mg, sodium chloride 5.8 mg, and citric acid 6.8 mg in water for injection.<sup>1(8/08)</sup>

Epoetin alfa is also available in 2-mL multidose (preserved) vials containing 10,000 units/mL and 1-mL multidose (preserved) vials containing 20,000 units/mL. The solution also contains in each mL albumin human 2.5 mg, sodium citrate 1.3 mg, sodium chloride 8.2 mg, citric acid 0.11 mg, and benzyl alcohol 1% in water for injection.<sup>1(8/08)</sup>

### pH

Single-use vials: from 6.6 to 7.2. Multidose vials: from 5.8 to 6.4.<sup>1(8/08)</sup>

### Tonicity

The injection is isotonic.<sup>1(8/08)</sup>

### Trade Name(s)

Epogen, Procrit

### Administration

Epoetin alfa is administered by intravenous or subcutaneous injection. For subcutaneous injection, epoetin alfa (single-dose) may be diluted at the time of administration with an equal quantity of bacteriostatic sodium chloride 0.9% containing benzyl alcohol 0.9% to help ameliorate local discomfort at the subcutaneous injection site.<sup>1(8/08)</sup> 4

### Stability

Epoetin alfa is a colorless solution. It should not be used if it contains particulate matter or is discolored. Intact vials should

be stored under refrigeration and protected from freezing.<sup>1(8/08)</sup> Although refrigerated storage is required, the manufacturer has stated the single-dose form may be stored at room temperature for 14 days while the multidose form may be stored at room temperature for seven days.<sup>2745</sup> To prevent foaming and inactivation, the product should not be shaken; vigorous prolonged shaking may denature the protein, inactivating it.<sup>1(8/08)</sup> 4 However, a small amount of flocculated protein in the solution does not affect potency. In addition, exposure to light for less than 24 hours does not adversely affect the product.<sup>4</sup>

The single-dose vials have no preservative. After a single dose has been removed from this product, the vial should not be re-entered and should be discarded.<sup>1(8/08)</sup> Drawn into plastic tuberculin syringes, the preservative-free products at 2000 or 10,000 units/mL are reported to be stable for two weeks at room temperature or under refrigeration. However, use shortly after drawing up in syringes is recommended because of the absence of preservative.<sup>4</sup>

Usually, epoetin alfa should not be diluted and transferred to new containers or admixed with other drugs and solutions because of possible protein loss from adsorption to PVC containers and tubing. However, when 10,000-unit/mL single-use product is diluted in the original vial with benzyl alcohol-preserved sodium chloride 0.9% injection to a concentration of 4000 units/mL for subcutaneous use, it is stated to be stable for at least 12 weeks stored at 5 and 30°C. Furthermore, the final benzyl alcohol concentration of 0.54% enabled the dilution to pass the USP preservative effectiveness test.<sup>1905</sup> Restriction of this dilution to 28 days used as a multiple-dose vial has been recommended.<sup>1906</sup> Higher concentrations of epoetin alfa (e.g., 5000 units/mL), which would have lower benzyl alcohol concentrations, were found to fail the preservative effectiveness test.<sup>1905</sup>

Epoetin alfa (Amgen) 20,000 units/1 mL was packaged in 1-mL hubless Medsaver (Becton Dickinson) plastic syringes and stored under refrigeration for six weeks. No loss of epoetin alfa biological activity was found.<sup>2472</sup>

The multidose vials contain a preservative and may be stored under refrigeration after initial dose removal. The vials should be discarded 21 days after initial entry.<sup>1(8/08)</sup>

## Epoprostenol Sodium

### AHFS 48:48

#### Products

Epoprostenol sodium is available as a lyophilized powder in vials containing 0.5 mg (500,000 ng) and 1.5 mg (1,500,000 ng) of epoprostenol.<sup>2879 2880 2881</sup> Several different formulations of epoprostenol sodium products are available; instructions for reconstitution and administration may differ, and epoprostenol stability may vary depending on formulation-specific factors.<sup>2879 2880 2881</sup>

Epoprostenol sodium (Flolan, Glaxo; generic, Teva) vials also contain glycine 3.76 mg, sodium chloride 2.93 mg, and mannitol 50 mg.<sup>2879 2881</sup> Sodium hydroxide may have been added during manufacturing to adjust the pH.<sup>2879 2881</sup> These epoprostenol sodium vials must be reconstituted and further diluted using only a special diluent that is recommended by the manufacturer.<sup>2879 2881</sup> Flolan must be reconstituted only with one of 2 special diluents, which are labeled as either "sterile diluent for Flolan" (in a 50-mL glass vial) or "pH 12 sterile diluent for Flolan" (in a 50-mL plastic vial).<sup>2879</sup> The choice of which of these 2 special diluents is used in the reconstitution and dilution of Flolan affects the drug's stability.<sup>2879</sup> (See Stability.) Epoprostenol sodium (Teva) must be reconstituted only with the sterile diluent that is labeled as "sterile diluent for epoprostenol sodium for injection" (in a 50-mL glass vial).<sup>2881</sup> Regardless of the formulation, these vials of special diluent contain glycine 94 mg, sodium chloride 73.3 mg, and sodium hydroxide to adjust the pH in water for injection.<sup>2879 2881</sup>

Epoprostenol sodium (Veletri, Actelion) has a differing formulation.<sup>2880</sup> In addition to epoprostenol sodium, vials of Veletri contain sucrose 100 mg, arginine 50 mg, and sodium hydroxide to adjust the pH.<sup>2880</sup> Vials of this formulation may be reconstituted with either sterile water for injection or sodium chloride 0.9% and further diluted with the same diluent used for reconstitution.<sup>2880</sup>

Each 0.5-mg (500,000-ng) or 1.5-mg (1,500,000-ng) vial of any formulation of epoprostenol sodium should be reconstituted with 5 mL of an appropriate diluent.<sup>2879 2880 2881</sup> The reconstituted solutions must be diluted prior to administration to provide a final concentration that is compatible with the maximum and minimum flow rates of the infusion pump, the reservoir capacity, and other infusion pump-specific criteria as stated by the manufacturers.<sup>2879 2880 2881</sup> In general, a 3000- to 10,000-ng/mL concentration of epoprostenol is sufficient to accommodate infusion rates of 2 to 16 ng/kg/min in adults, although higher concentrations may be required for some patients.<sup>2879 2880 2881</sup>

The manufacturers' instructions for preparing various concentrations of epoprostenol from the reconstituted solution using the identical diluent that was used for reconstitution are as follows:<sup>2879 2880 2881</sup>

For 3000 ng/mL, withdraw 3 mL from one 0.5-mg (500,000-ng) vial and add a sufficient amount of diluent to make a total of 100 mL.

For 5000 ng/mL, withdraw the entire contents of one 0.5-mg (500,000-ng) vial and add a sufficient amount of diluent to make a total of 100 mL.

For 10,000 ng/mL, withdraw the entire contents of two 0.5-mg (500,000-ng) vials and add a sufficient amount of diluent to make a total of 100 mL.

For 15,000 ng/mL, withdraw the entire contents of one 1.5-mg (1,500,000-ng) vial and add a sufficient amount of diluent to make a total of 100 mL.

For 30,000 ng/mL, withdraw the entire contents of two 1.5-mg (1,500,000-ng) vials and add a sufficient amount of diluent to make a total of 100 mL.<sup>2880</sup>

The manufacturers state that higher concentrations of the drug may be prepared for those receiving long-term therapy.<sup>2879 2880 2881</sup>

#### pH

Sterile diluent for Flolan has a pH ranging from 10.2 to 10.8; pH 12 sterile diluent for Flolan has a pH ranging from 11.7 to 12.3.<sup>2879</sup>

Reconstituted solutions of epoprostenol (Teva) prepared with the provided sterile diluent for epoprostenol sodium for injection have a pH ranging from 11 to 11.8.<sup>2881</sup>

Reconstituted solutions of Veletri have a pH ranging from 11 to 13.<sup>2880</sup>

#### Trade Name(s)

Flolan, Veletri

#### Administration

Following reconstitution and dilution to the selected final concentration, epoprostenol solution is administered by continuous intravenous infusion through a central venous catheter using an ambulatory infusion pump.<sup>2879 2880 2881</sup> The drug may be given temporarily by peripheral infusion until a central line can be established.<sup>2879 2880 2881</sup> The pump reservoirs used should be made of polyvinyl chloride (PVC), polypropylene, or glass.<sup>2879 2880 2881</sup>

Epoprostenol solutions prepared with sterile diluent for Flolan or sterile diluent for epoprostenol sodium for injection must be used with a cold pouch if not administered within 8 hours of reconstitution or removal from refrigeration.<sup>2879 2881</sup> (See Stability.)

#### Stability

##### Epoprostenol Sodium (Flolan, Glaxo)

Intact vials of the Flolan formulation of epoprostenol sodium should be stored at 15 to 25°C in the carton to protect from light.<sup>2879</sup> Intact vials of sterile diluent for Flolan and pH 12 sterile diluent for Flolan also should be stored at 15 to 25°C and should not be frozen.<sup>2879</sup> Flolan must be reconstituted and diluted

only with one of these 2 diluents; the reconstituted epoprostenol solutions should not be diluted or administered with other parenteral solutions or medications.<sup>2879</sup> If not used immediately following preparation, these solutions of epoprostenol should be refrigerated at 2 to 8°C and protected from light.<sup>2879</sup> The solutions should *not* be frozen; any solution that has been frozen should be discarded.<sup>2879</sup> Solutions should be visually inspected for particulate matter and discoloration and should not be used if either is noted.<sup>2879</sup> Vials are for single dose only; any unused solution or diluent should be discarded.<sup>2879</sup>

Epoprostenol solutions prepared with sterile diluent for Flolan are stable for up to 8 hours when used at 15 to 25°C following reconstitution.<sup>2879</sup> These solutions may be stored for up to 40 hours at 2 to 8°C prior to use and are stable for up to 8 hours when used at 15 to 25°C following removal from refrigeration; solutions should be discarded after more than 40 hours of refrigerated storage.<sup>2879</sup> Solutions prepared with sterile diluent for Flolan must be used with a cold pouch if not administered within 8 hours.<sup>2879</sup> These solutions may be stored for up to 24 hours at 2 to 8°C prior to use and are stable for up to 24 hours when used with a cold pouch that is changed every 12 hours.<sup>2879</sup> Solutions may be stored at 2 to 8°C prior to use as long as the total combined time of refrigerated storage and infusion does not exceed 48 hours; solutions should be discarded after more than 48 hours of refrigerated storage.<sup>2879</sup>

Epoprostenol solutions prepared with *pH 12* sterile diluent for Flolan may be administered for up to 72 hours at up to 25°C, 48 hours at up to 30°C, 24 hours at up to 35°C, or 12 hours at up to 40°C, either immediately following preparation or following refrigerated storage at 2 to 8°C for up to 8 days; these solutions do *not* require the use of a cold pouch during administration.<sup>2879</sup> Solutions prepared with *pH 12* sterile diluent for Flolan should be discarded after 8 days of refrigerated storage.<sup>2879</sup>

### Epoprostenol Sodium (Teva)

Intact vials of this formulation of epoprostenol sodium should be stored at 20 to 25°C in the carton to protect from light.<sup>2881</sup> Intact vials of sterile diluent for epoprostenol sodium for injection also should be stored at 20 to 25°C and should *not* be frozen.<sup>2881</sup> This epoprostenol sodium formulation must be reconstituted and diluted only with sterile diluent for epoprostenol sodium for injection; the reconstituted epoprostenol solutions should not be diluted or administered with other parenteral medications or solutions.<sup>2881</sup> If not used immediately following preparation, these solutions of epoprostenol should be refrigerated at 2 to 8°C and protected from light.<sup>2881</sup> The solutions should *not* be frozen; any solution that has been frozen should be discarded.<sup>2881</sup> Solutions should be visually inspected for particulate matter and discoloration and should not be used if either is noted.<sup>2881</sup> Vials are for single dose only; any unused solution or diluent should be discarded.<sup>2881</sup>

Epoprostenol solutions prepared with sterile diluent for epoprostenol sodium for injection are stable for up to 8 hours when used at 15 to 25°C following reconstitution.<sup>2881</sup> These solutions may be stored for up to 40 hours at 2 to 8°C prior to use and are stable for up to 8 hours when used at 15 to 25°C following removal from refrigeration; solutions should be

discarded after more than 40 hours of refrigerated storage.<sup>2881</sup> Solutions prepared with sterile diluent for epoprostenol sodium for injection must be used with a cold pouch if not administered within 8 hours.<sup>2881</sup> These solutions may be stored for up to 24 hours at 2 to 8°C prior to use and are stable for up to 24 hours when used with a cold pouch that is changed every 12 hours.<sup>2881</sup> Solutions may be stored at 2 to 8°C prior to use as long as the total combined time of refrigerated storage and infusion does not exceed 48 hours; solutions should be discarded after more than 48 hours of refrigerated storage.<sup>2881</sup>

### Epoprostenol Sodium (Veletri, Actelion)

Intact vials of the Veletri formulation of epoprostenol sodium should be stored at 20 to 25°C in the carton and protected from direct sunlight.<sup>2880</sup> The manufacturer states that this formulation of epoprostenol sodium is stable only when reconstituted and diluted as directed with sterile water for injection or sodium chloride 0.9%; the drug should not be mixed with any other drugs or solutions prior to or during administration.<sup>2880</sup> Solutions should be visually inspected for particulate matter and discoloration and should not be used if either is noted.<sup>2880</sup> Vials are for single use only; any unused solution should be discarded.<sup>2880</sup>

For administration at 25°C, reconstituted and diluted epoprostenol solutions of 3000 to less than 15,000 ng/mL (prepared as directed using 0.5-mg [500,000-ng] vials) may be administered for a maximum duration of 48 hours beginning immediately after reconstitution and dilution or a maximum duration of 24 hours after storage under refrigeration at 2 to 8°C for up to 8 days.<sup>2880</sup> Solutions of 15,000 to less than 60,000 ng/mL (prepared as directed using 1.5-mg [1,500,000-ng] vials) may be administered at 25°C for a maximum duration of 48 hours beginning either immediately after reconstitution and dilution or after storage under refrigeration at 2 to 8°C for up to 8 days.<sup>2880</sup> Solutions of 60,000 ng/mL or more (prepared using 1.5-mg [1,500,000-ng] vials) may be administered at 25°C for a maximum duration of 72 hours beginning immediately after reconstitution and dilution or a maximum duration of 48 hours after storage under refrigeration at 2 to 8°C for up to 8 days.<sup>2880</sup> Short excursions at 40°C are permitted for up to 2, 4, or 8 hours for solutions of less than 15,000 ng/mL, 15,000 to 60,000 ng/mL, or greater than 60,000 ng/mL, respectively.<sup>2880</sup>

Epoprostenol solutions of 60,000 ng/mL or more (prepared using 1.5-mg [1,500,000-ng] vials) may be administered at temperatures greater than 25°C up to 30°C for a maximum duration of 48 hours, either beginning immediately after reconstitution and dilution or after refrigeration at 2 to 8°C for up to 8 days.<sup>2880</sup> Such solutions also may be administered at temperatures up to 40°C for a maximum duration of 24 hours immediately after reconstitution and dilution.<sup>2880</sup> For solutions with a concentration less than 60,000 ng/mL, the pump reservoir should be changed every 24 hours.<sup>2880</sup>

### *pH Effects*

Epoprostenol is best stabilized in basic solutions,<sup>2882</sup> and the reconstituted solution becomes increasingly unstable at pH values below the respective normal ranges of each formulation.<sup>2880</sup> <sup>2881</sup> Veletri uses arginine as a buffer, which provides a higher pH than that provided by the glycine buffer in other

epoprostenol sodium products (Glaxo, Teva) and likely contributes to the relative improvement in stability.<sup>2879 2880 2881 2882</sup> Flolan prepared with the provided *pH 12* sterile diluent for Flolan results in a reconstituted solution with a higher pH than if prepared with the alternative provided sterile diluent for Flolan and demonstrates increased stability as a result.<sup>2879</sup>

### Light Effects

Epoprostenol sodium (Flolan, Glaxo; generic, Teva) as unopened vials and reconstituted solutions should be protected from light during storage.<sup>2879 2881</sup> The manufacturer of Veletri notes that

this formulation of epoprostenol sodium should not be exposed to direct sunlight either in the unopened vial during storage or in solution.<sup>2880</sup>

### Filtration

A 60-inch microbore non-diethylhexyl phthalate (non-DEHP) extension set with proximal antisyphon valve, low priming volume (0.9 mL), and inline 0.22- $\mu$ m filter was used during trials with epoprostenol<sup>2880 2881</sup> and is recommended for Flolan administration.<sup>2879</sup> Infusion sets with an inline 0.22- $\mu$ m filter should be used for the administration of Veletri.<sup>2880</sup>

## Eptifibatide

AHFS 20:12.18

### Products

Eptifibatide is available at a concentration of 2 mg/mL in 10- and 100-mL vials and at a concentration of 0.75 mg/mL in 100-mL vials.<sup>3048</sup> Each mL of injection also contains citric acid 5.25 mg and sodium hydroxide to adjust the pH.<sup>3048</sup>

### pH

The pH is adjusted to near 5.35 during manufacturing.<sup>3048</sup>

### Trade Name(s)

Integrilin

### Administration

Eptifibatide is administered by intravenous bolus (push) injection; the appropriate dose should be withdrawn from the 10-mL vial.<sup>3048</sup> The bolus dose should be followed immediately by a continuous intravenous infusion; using an infusion pump, the

appropriate concentration of eptifibatide in a 100-mL vial should be spiked with a vented infusion set and administered directly (undiluted) at a rate that is appropriate for the specific patient.<sup>3048</sup> For some indications, a second bolus injection of eptifibatide is administered 10 minutes after the initial bolus.<sup>3048</sup>

### Stability

Intact vials of eptifibatide should be stored under refrigeration and protected from light until the time of administration.<sup>3048</sup> The drug may be stored for up to 2 months at room temperature; the cartons of the vials stored at room temperature should be marked with a "DISCARD BY" date of 2 months after transfer to room temperature storage or the expiration date, whichever comes first.<sup>3048</sup>

### pH Effects

The minimum rate of decomposition occurs in the pH range of 5 to 6.<sup>2417</sup>

## Eravacycline Dihydrochloride

AHFS 8:12.24.08

### Products

Eravacycline dihydrochloride is available as a lyophilized powder in single-dose (preservative-free) vials containing the equivalent of 50 mg of eravacycline and 150 mg of mannitol in each vial.<sup>3434</sup> Each vial also may contain sodium hydroxide and hydrochloric acid for pH adjustment.<sup>3434</sup>

Each 50-mg vial should be reconstituted with 5 mL of sterile water for injection or sodium chloride 0.9% to yield a reconstituted solution with an eravacycline concentration of 10 mg/mL.<sup>3434</sup> During reconstitution, vials should be swirled gently to completely dissolve the vial contents; shaking or rapid movement should be avoided as it may cause foaming.<sup>3434</sup> If any particles are present or if cloudiness is observed, the reconstituted solution should not be used.<sup>3434</sup> The reconstituted solution must be further diluted prior to administration.<sup>3434</sup> The appropriate volume of the reconstituted solution should be withdrawn from the vial(s) and diluted in an infusion bag containing sodium chloride 0.9% for a target eravacycline concentration of 0.3 mg/mL (within the range of 0.2 to 0.6 mg/mL).<sup>3434</sup> The infusion bag should not be shaken.<sup>3434</sup> The diluted solution for infusion also should be visually inspected for particulate matter and discoloration prior to administration.<sup>3434</sup> Unused portions of reconstituted or diluted solutions should be discarded.<sup>3434</sup>

### pH

The pH is adjusted to the range of 5.5 to 7.<sup>3434</sup>

### Equivalency

Eravacycline dihydrochloride 63.5 mg is equivalent to 50 mg of eravacycline.<sup>3434</sup>

### Trade Name(s)

Xerava

## Compatibility Information

### Solution Compatibility

#### Eravacycline dihydrochloride

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Sodium chloride 0.9%		TET	200 to 600 mg	Infuse within 24 hr if stored at room temperature up to 25°C or 7 days if stored at 2 to 8°C	3434	C

#### Eravacycline dihydrochloride

Test Drug	Mfr	Conc	Mfr	Conc	Remarks	Ref	C/I
Albumin human	BXT	250 mg/mL	TET	0.6 mg/mL <sup>a</sup>	Measured turbidity increased immediately	3532	I
Amiodarone HCl	MYL	2 mg/mL <sup>a</sup>	TET	0.6 mg/mL <sup>a</sup>	Measured turbidity increased immediately	3532	I

### Administration

Eravacycline dihydrochloride is administered by intravenous infusion over 60 minutes after reconstitution and further dilution.<sup>3434</sup> The reconstituted solution is *not* for direct injection.<sup>3434</sup>

Eravacycline dihydrochloride may be administered intravenously through a dedicated line or through a Y-site.<sup>3434</sup> If the intravenous line is used to administer other drugs, it should be flushed with sodium chloride injection 0.9% prior to and following eravacycline dihydrochloride administration.<sup>3434</sup>

### Stability

Eravacycline dihydrochloride lyophilized powder is a yellow to orange powder that forms a clear, pale yellow to orange solution upon reconstitution and a clear, light yellow to orange solution upon dilution.<sup>3434</sup> Intact vials of eravacycline dihydrochloride should be stored at 2 to 8°C in the original carton until time of use.<sup>3434</sup>

The manufacturer states that the drug should not be mixed with any other drugs or solutions.<sup>3434</sup>

The reconstituted solution may be stored for up to 1 hour after reconstitution at room temperature up to 25°C, but should be diluted in an infusion bag within 1 hour after reconstitution.<sup>3434</sup> Admixtures prepared as directed from the lyophilized powder should be infused within 7 days if stored at 2 to 8°C or 24 hours if stored at room temperature up to 25°C.<sup>3434</sup>

### Freezing Solutions

The manufacturer states that neither the reconstituted nor diluted solutions should be frozen.<sup>3434</sup>

## Eribulin Mesylate

AHFS 10:00

### Products

Eribulin mesylate is available as a 0.5-mg/mL solution in 2-mL single-use vials containing a total of eribulin mesylate 1 mg (equivalent to eribulin 0.88 mg), dehydrated alcohol 5% (v/v), and water for injection 95% (v/v).<sup>3027 3028</sup> Sodium hydroxide and/or hydrochloric acid may have been added during manufacturing to adjust the pH.<sup>2805 3028</sup>

### pH

From 6.5 to 8.5.<sup>2805</sup>

### Trade Name(s)

Halaven

### Administration

Eribulin mesylate is administered intravenously over 2 to 5 minutes.<sup>3027</sup> The drug may be administered undiluted or diluted in 100 mL of sodium chloride 0.9%.<sup>3027</sup>

Eribulin mesylate should not be diluted in dextrose-containing solutions nor administered through an intravenous line that is infusing dextrose-containing solutions.<sup>3027</sup>

### Stability

Intact vials should be stored at controlled room temperature in the original carton; vials should not be refrigerated nor frozen.<sup>3027</sup> Eribulin mesylate is a clear, colorless solution.<sup>3027</sup>

The manufacturer states that undiluted eribulin mesylate may be stored in a syringe for up to 4 hours at room temperature or up to 24 hours at 4°C.<sup>3027</sup> Similarly, diluted solutions of eribulin mesylate may be stored for up to 4 hours at room temperature or 24 hours under refrigeration.<sup>3027</sup> Unused portions remaining in the vials should be discarded.<sup>3027</sup>

Stability of the undiluted product (Eisai) was tested in the original glass vial with light protection at 25°C and at 2 to 8°C.<sup>3028</sup> The solution was found to be physically compatible and chemically stable with little to no loss in 28 days.<sup>3028</sup>

### pH Effects

Eribulin mesylate stability is pH dependent.<sup>3028</sup> The drug has been noted to be stable over a pH range of 5 to 9.<sup>3028</sup> Mixing eribulin mesylate with dextrose-containing solutions is not recommended given the acid sensitivity of the drug.<sup>3027 3028</sup>

### Syringes

Eribulin mesylate (Eisai) 205 mcg/mL in sodium chloride 0.9% packaged in 10-mL polypropylene syringes (Becton Dickinson) was physically compatible and chemically stable with little to no loss in 28 days stored with light protection at 25 and 2 to 8°C.<sup>3028</sup>

## Ertapenem Sodium

AHFS 8:12.07.08

### Products

Ertapenem is available as a lyophilized powder in 1-g single-use vials as the sodium salt with sodium bicarbonate 175 mg and sodium hydroxide to adjust the pH.<sup>2973</sup> For intravenous administration, reconstitute the contents of a 1-g vial with 10 mL of sterile water for injection, bacteriostatic water for injection, or sodium chloride 0.9% and shake well,<sup>2973</sup> yielding a concentration of 100 mg/mL.<sup>2975</sup> For adult patients, immediately transfer the appropriate dose of the reconstituted solution to 50 mL of sodium chloride 0.9%.<sup>2973</sup> For pediatric patients, transfer the appropriate dose of reconstituted solution to a volume of sodium chloride 0.9% that is sufficient to yield a final concentration of 20 mg/mL or less.<sup>2973</sup>

Ertapenem also is available as a lyophilized powder in 1-g single-use ADD-Vantage vials as the sodium salt.<sup>2973</sup> Each ADD-Vantage vial also contains sodium bicarbonate 175 mg and sodium hydroxide to adjust the pH.<sup>2973</sup> Prepare ADD-Vantage vials of ertapenem sodium with 50 or 100 mL of sodium chloride 0.9% in ADD-Vantage diluent containers.<sup>2973</sup>

For intramuscular injection, reconstitute the contents of a 1-g vial with 3.2 mL of lidocaine hydrochloride 1% (without epinephrine) and shake well,<sup>2973</sup> yielding a final volume of approximately 3.6 mL and a concentration of approximately 280 mg/mL.<sup>2975</sup> Upon dissolution, administer within 1 hour.<sup>2973</sup> Do *not* administer the reconstituted intramuscular injection intravenously.<sup>2973</sup>

### pH

7.5.<sup>2973</sup>

### Sodium Content

Each 1-g vial contains approximately 137 mg or 6 mEq of sodium.<sup>2973</sup>

### Trade Name(s)

Invanz

### Administration

Ertapenem sodium diluted in sodium chloride 0.9% may be administered by intravenous infusion over 30 minutes.<sup>2973</sup> Ertapenem sodium prepared with lidocaine hydrochloride 1% for intramuscular administration may be administered by deep intramuscular injection into a large muscle mass (e.g., gluteal muscle, lateral part of the thigh).<sup>2973</sup>

### Stability

Intact vials of ertapenem sodium should be stored at a temperature not exceeding 25°C.<sup>2973</sup> The reconstituted drug solution for intravenous administration should be diluted immediately in sodium chloride 0.9%,<sup>2973</sup> but has been noted to remain stable in the vial for 2 hours at 25°C or 6 hours at 5°C when reconstituted with sterile water for injection, sodium chloride 0.9%, bacteriostatic water with benzyl alcohol 0.9%, or Ringer's injection, lactated.<sup>2975</sup> The manufacturer recommends that solutions of ertapenem not be frozen.<sup>2973</sup>

Dextrose-containing solutions should *not* be used to dilute ertapenem<sup>2973</sup> as an unacceptable loss due to degradation has been observed with their use; however, limited contact over a short period of time (e.g., ertapenem run as a piggyback into the same line as dextrose) should not adversely affect ertapenem stability.<sup>2975</sup>

Ertapenem diluted for infusion from both single-use vials and ADD-Vantage single-use vials may be stored and used within 6 hours at room temperature or may be stored for 24 hours under refrigeration and used within 4 hours after removal from refrigeration.<sup>2973</sup>

Ertapenem prepared for intramuscular administration should be used within 1 hour.<sup>2973</sup>

### Freezing Solutions

The manufacturer recommends that solutions of ertapenem not be frozen due to degradation of the drug.<sup>2973 2975</sup>

Ertapenem (Merck) 100 mg/mL in sodium chloride 0.9% in polypropylene syringes was frozen at -20°C for 14 or 28 days immediately after preparation, followed by thawing at room temperature for 1 hour.<sup>2974</sup> Upon thawing for 1 hour, the solution frozen for 28 days was found to have undergone about 5% loss.<sup>2974</sup> The solution frozen for 14 days was found to have undergone about 7% loss after 5 hours at room temperature (including the 1 hour of thawing time).<sup>2974</sup>

### Syringes

Ertapenem (Merck) 100 mg/mL in sodium chloride 0.9% was packaged as 10 mL in 20-mL polypropylene syringes (Monoject).<sup>2974</sup> The drug was found to be stable for approximately 30 minutes at room temperature or 24 hours under refrigeration followed by up to 4 hours at room temperature after removal from refrigeration.<sup>2974</sup>

## Compatibility Information

# Erythromycin Lactobionate

AHFS 8:12.12.04

## Products

Erythromycin lactobionate is available in vials containing the equivalent of 1 g of erythromycin and in vials containing the equivalent of 500 mg of erythromycin. Reconstitute the 1-g vials with at least 20 mL and the 500-mg vials with 10 mL of sterile water for injection without preservatives. The resultant concentration is 5% (50 mg/mL). The drug is also available in 500-mg and 1-g ADD-Vantage vials without preservative.<sup>1(11/06) 4</sup>

## pH

Reconstitution with sterile water for injection to a 50-mg/mL concentration results in a solution with a pH of 6.5 to 7.5.<sup>20</sup>

## Osmolality

Erythromycin lactobionate 50 mg/mL in sterile water for injection has an osmolality of 223 mOsm/kg.<sup>50</sup>

The osmolality of erythromycin lactobionate was calculated for the following dilutions:<sup>1054</sup>

Diluent	Osmolality (mOsm/kg)	
	50 mL	100 mL
500 mg		
Dextrose 5%	273	265
Sodium chloride 0.9%	299	291
1 g		
Dextrose 5%	287	273
Sodium chloride 0.9%	313	300

## Trade Name(s)

Erythrocin Lactobionate-I.V.

## Administration

Erythromycin lactobionate may be administered by continuous or intermittent intravenous infusion; it must not be given by direct intravenous injection. To minimize venous irritation, slow continuous infusion of a 1-mg/mL concentration is recommended. By intermittent infusion, one-fourth of the daily dose at a concentration of 1 to 5 mg/mL in at least 100 mL of infusion solution may be given over 20 to 60 minutes every 6 hours.<sup>1(11/06) 4</sup>

## Stability

Do not use sodium chloride 0.9% or other solutions containing inorganic ions in the initial reconstitution of the regular vials. Such solutions result in the formation of a precipitate.<sup>4 20</sup> (Note: This restriction does not apply to the drug in ADD-Vantage containers.)

The commercial vials are stable at room temperature.<sup>20</sup> Reconstituted (5%) solutions are stable for 14 days when stored under refrigeration<sup>20</sup> or for 24 hours when kept at room temperature.<sup>1(11/06)</sup>

## pH Effects

The stability of erythromycin lactobionate is extremely pH dependent. It is most stable at pH 6 to 8<sup>20 1935</sup> or 9.<sup>1101 2596</sup> Erythromycin lactobionate is unstable in acidic solutions. Decomposition occurs at an increasingly more rapid rate as the pH approaches 4.<sup>20</sup> A pH over 5.5 is recommended for the final diluted solution. At pH 5.5 or below and at pH 10 or above, erythromycin lactobionate is particularly unstable, with 10% decomposition occurring in about eight or nine hours. The following pH profile was determined for erythromycin in solution:<sup>1101</sup>

Solution pH	Approximate Time for 10% Decomposition ( $t_{90}$ )
5	2.5 hr
5.5	8.8 hr
6	1 day
7	4.6 days
8	7.3 days
9	2.6 days
10	8.8 hr
11	53 min

Erythromycin lactobionate can alter the pH of solutions and give itself some protection against decomposition for varying periods. The length of time is dependent on the initial pH and the buffer capacity of the solution.<sup>48</sup> The pH of unbuffered dextrose 5% is raised 1 pH unit by the addition of erythromycin lactobionate.<sup>20</sup> The use of admixtures with a pH of less than 5 is not recommended. If the admixture pH is 5 to 6, it should be used immediately.<sup>48</sup>

The effect of buffering erythromycin lactobionate (Abbott) solutions was evaluated. Erythromycin lactobionate 2 mg/mL in sodium chloride 0.9% (pH 7.15 to 7.25) exhibited 5% losses in about 20 days at 5°C. However, buffering with sodium bicarbonate to pH 7.5 to 8 extended stability, with 5% losses occurring in about 85 days at 5°C.<sup>1587</sup>

## Freezing Solutions

Erythromycin lactobionate (Abbott) 500 mg/110 mL in sodium chloride 0.9% in PVC bags was frozen at -20°C; no loss occurred after 12 months of storage followed by microwave thawing. Furthermore, the solution was physically compatible, with no increase in subvisible particles. In addition, no erythromycin loss was found after 6 months at -20°C followed by 3 freeze-thaw cycles.<sup>1612</sup>

# Esmolol Hydrochloride

AHFS 24:24

## Products

Esmolol hydrochloride is available as a 10-mg/mL premixed, ready-to-use solution in 10-mL single-dose (preservative-free) vials and 250-mL bags.<sup>2869 3234</sup> Each mL of the ready-to-use solution also contains sodium acetate trihydrate 2.8 mg and glacial acetic acid 0.546 mg in water for injection with or without sodium chloride 5.9 mg, and may contain sodium hydroxide and/or hydrochloric acid for pH adjustment during manufacturing.<sup>2869 3234</sup> Vials may be used to prepare loading doses for administration by hand-held syringe while the maintenance infusion is being readied.<sup>2869 3234</sup>

Esmolol hydrochloride also is available as a double-strength 20-mg/mL premixed, ready-to-use solution in 100-mL bags.<sup>2869</sup> Each mL of the double-strength ready-to-use solution also contains sodium chloride 4.1 mg, sodium acetate trihydrate 2.8 mg, and glacial acetic acid 0.546 mg, and also may contain sodium hydroxide and/or hydrochloric acid for pH adjustment during manufacturing.<sup>2869</sup>

Esmolol hydrochloride (WG Critical Care) is available as a premixed, ready-to-use, preservative-free solution at a concentration of 10 mg/mL in 250-mL bags and 20 mg/mL (double strength) in 100-mL bags intended for single-patient use.<sup>3235</sup> Each mL of the ready-to-use solution also contains ethanol 1.23% (v/v), propylene glycol 10 mg, sodium acetate trihydrate 0.68 mg, and glacial acetic acid 0.27 mg in water for injection, and may contain sodium hydroxide for pH adjustment during manufacturing.<sup>3235</sup>

## pH

Esmolol hydrochloride 10- and 20-mg/mL solutions (Brevibloc, Baxter; generic) have a pH ranging from 4.5 to 5.5.<sup>2869 3234</sup>

Esmolol hydrochloride 10- and 20-mg/mL solutions (WG Critical Care) have a pH ranging from 4.5 to 6.5.<sup>3235</sup>

## Osmolarity

Esmolol hydrochloride 10- and 20-mg/mL solutions (Brevibloc, Baxter) are iso-osmotic having an osmolarity of 312 mOsm/L.<sup>2869</sup>

Esmolol hydrochloride 10- and 20-mg/mL solutions (WG Critical Care) have an osmolarity of 320 to 450 mOsm/L and 440 to 500 mOsm/L, respectively.<sup>3235</sup>

## Trade Name(s)

Brevibloc

## Administration

Esmolol hydrochloride may be administered as a continuous infusion at a concentration of 10 or 20 mg/mL with or without a loading dose administered by intravenous bolus injection over 30 to 60 seconds.<sup>2869 3234 3235</sup>

Esmolol hydrochloride may cause serious venous irritation, including thrombophlebitis, and more serious local reactions, including skin necrosis and blistering, especially when associated with extravasation.<sup>2869 3234 3235</sup> The manufacturer recommends avoiding infusions into a small vein or through a butterfly catheter.<sup>2869 3234 3235</sup> If a local infusion site reaction develops, an alternative infusion site should be used; extravasation should be avoided.<sup>2869 3234 3235</sup>

## Stability

Esmolol hydrochloride is a clear, colorless to light yellow solution.<sup>2869 3234 3235</sup> Intact vials and bags should be stored at controlled room temperature and protected from elevated temperatures and freezing.<sup>2869 3234 3235</sup> Bags should remain in their overwrap until ready for use.<sup>2869 3235</sup>

Esmolol hydrochloride solutions should be visually inspected for particulate matter and discoloration prior to administration.<sup>2869 3234 3235</sup> Following withdrawal of solution from the bag (e.g., a bolus dose), infusion of the remaining solution should begin immediately and any unused portion not infused by 24 hours after withdrawal from the bag should be discarded.<sup>2869 3235</sup>

## pH Effects

Esmolol hydrochloride is relatively stable at neutral pH; the optimal pH is 4.5 to 5.5. However, ester hydrolysis occurs rapidly in strongly acidic or basic solutions.<sup>1358 1359</sup>

## Esomeprazole Sodium

AHFS 56:28.36

### Products

Esomeprazole is available as a lyophilized powder in 20- and 40-mg vials as the sodium salt with edetate disodium 1.5 mg and sodium hydroxide to adjust pH during manufacturing. For direct intravenous injection, reconstitute either size vial with 5 mL of sodium chloride 0.9%.<sup>1(3/05)</sup>

For intravenous infusion, reconstitute either size vial with 5 mL of sodium chloride 0.9%; Ringer's injection, lactated; or dextrose 5%, and then dilute the reconstituted solution to 50 mL with additional infusion solution.<sup>1(3/05)</sup>

### pH

From 9 to 11.<sup>1(3/05)</sup>

### Trade Name(s)

Nexium I.V.

### Administration

Esomeprazole sodium is administered by direct intravenous injection over at least 3 minutes or by intravenous infusion over 10 to 30 minutes.<sup>1(3/05)</sup>

### Stability

Intact vials of esomeprazole sodium should be stored at controlled room temperature and protected from light. The

drug reconstituted with sodium chloride 0.9% for direct intravenous injection should be administered within 12 hours after reconstitution when stored at room temperature. Esomeprazole sodium reconstituted and diluted for intravenous infusion should be administered within 12 hours at room temperature after reconstitution and dilution if sodium chloride 0.9% or Ringer's injection, lactated, is the reconstitution and dilution solution. If dextrose 5% is used for reconstitution and dilution, the drug should be used within 6 hours at room temperature. The manufacturer states that refrigeration is not required for esomeprazole solutions.<sup>1(3/05)</sup>

The manufacturer states that esomeprazole sodium administration requires flushing the administration line with sodium chloride 0.9%; Ringer's injection, lactated; or dextrose 5% both before and after administering the drug, and that esomeprazole sodium should not be administered concomitantly with other drugs.<sup>1(3/05)</sup>

### pH Effects

The stability of esomeprazole sodium in solution is strongly dependent on pH. The stability of the drug decreases with decreasing pH.<sup>1(3/05)</sup>

## Estrogens, Conjugated

AHFS 68:16.04

### Products

Estrogens, conjugated is available in packages containing a vial with lyophilized estrogens, conjugated, 25 mg; lactose 200 mg; sodium citrate 12.2 mg; simethicone 0.2 mg; and sodium hydroxide or hydrochloric acid for pH adjustment. Reconstitute the vial with 5 mL of sterile water for injection flowing along the side of the vial and agitate gently – not violently.<sup>1(3/08)</sup>

### Trade Name(s)

Premarin Intravenous

### Administration

Estrogens, conjugated may be administered by deep intramuscular injection or slow direct intravenous injection. Intravenous

infusion is not recommended, but injection into the tubing of a running infusion may be performed.<sup>1(3/08)</sup> 4

### Stability

The manufacturer recommends refrigeration of the intact containers at 2 to 8°C.<sup>1(3/08)</sup> Such storage provides a shelflife of up to 60 months. Although refrigerated storage is required, the manufacturer has stated the drug may be stored at room temperature for seven days.<sup>2745</sup> The manufacturer recommends use immediately after reconstitution.<sup>1(3/08)</sup>

### pH Effects

Estrogens, conjugated, has been stated to be incompatible with any solution with an acid pH.<sup>1(3/08)</sup> 4

## Ethacrynate Sodium

AHFS 40:28.08

### Products

Each vial has ethacrynate sodium equivalent to ethacrynic acid 50 mg and mannitol 62.5 mg. Reconstitute with 50 mL of dextrose 5% or sodium chloride 0.9% to yield a 1-mg/mL solution. Some dextrose 5% has a pH below 5 and results in a hazy or opalescent solution, which is not recommended for use.<sup>1(2/05) 4</sup>

### pH

Reconstitution with dextrose 5% or sodium chloride 0.9% results in a solution having a pH of 6.3 to 7.7.<sup>4</sup>

### Sodium Content

Ethacrynate sodium contains 0.165 mEq of sodium per 50 mg of ethacrynic acid equivalent.<sup>846</sup>

### Trade Name(s)

Sodium Edecrin

### Administration

Ethacrynate sodium may be given slowly through the tubing of a running intravenous solution or directly into a vein over several minutes.<sup>1(2/05) 4</sup> Subcutaneous or intramuscular injection should not be used because of local pain and irritation.<sup>1(2/05) 4</sup>

### Stability

Solutions of ethacrynate sodium are relatively stable for short periods at pH 7 at room temperature; but as the pH or temperature or both increase, the solutions are less stable. Ethacrynate sodium is incompatible with solutions or drugs with a final pH below 5. The reconstituted solution should be discarded after 24 hours.<sup>1(2/05) 4</sup>

# Etomidate

AHFS 28:04.92

## Products

Etomidate injection is available as a 2-mg/mL solution in 10- and 20-mL single-dose vials and ampuls and 20-mL syringes.<sup>3319</sup> Each mL of etomidate injection also contains propylene glycol 35% (v/v).<sup>3319</sup>

### pH

From 4 to 7.<sup>3319</sup>

### Trade Name(s)

Amidate

## Administration

Etomidate is administered only by the intravenous route as an injection over 30 to 60 seconds.<sup>3319</sup> Manufacturers state that the drug should *not* be administered by prolonged infusion.<sup>3319</sup>

## Stability

Intact containers of etomidate should be stored at controlled room temperature.<sup>3319</sup>

Etomidate injection should be visually inspected for particulate matter and discoloration prior to administration; the solution should not be used unless it is clear and the container is undamaged.<sup>3319</sup> Unused portions should be discarded.<sup>3319</sup>

# Etoposide

## AHFS 10:00

### Products

Etoposide 20 mg/mL concentrate for injection is available in 5-, 25-, and 50-mL multiple-dose vials.<sup>2951</sup> Each mL also contains polyethylene glycol 300 650 mg, ethanol 30.5% (v/v), polysorbate 80 80 mg, benzyl alcohol 30 mg, and citric acid 2 mg.<sup>2951</sup>

### pH

From 3 to 4.<sup>2951</sup>

### Administration

Etoposide concentrate for injection must be diluted to a final concentration of 0.2 to 0.4 mg/mL prior to administration.<sup>2951</sup> The drug is recommended to be given by slow intravenous infusion over at least 30 to 60 minutes; however, a longer duration of administration may be considered if the volume of the infusion solution is a concern.<sup>2951</sup>

Continuous intravenous infusion also has been used.<sup>4</sup> The drug should *not* be given by rapid intravenous injection.<sup>2951</sup>

The surfactant content of the etoposide formulation decreases surface tension and has been found to produce a 30% reduction in drop size compared to simple aqueous solutions. The altered drop size may interfere with accurate infusion rates if infusion devices that rely on drop counting are used. The use of infusion devices that operate independently of drop size has been recommended.<sup>181</sup>

The manufacturer notes that accidental exposure to this potentially toxic agent may cause skin reactions.<sup>2951</sup> Therefore, protective gloves should be used during preparation of solutions.<sup>2951</sup> A soap and water wash should be employed after accidental contact with the skin and accidentally exposed mucosa should be flushed with water.<sup>2951</sup>

In the event of spills or leaks, the use of sodium hypochlorite 5% (household bleach) or potassium permanganate 1% to inactivate etoposide has been recommended.<sup>1200</sup>

### Stability

Etoposide concentrate for injection is a clear yellow solution.<sup>2951</sup> Intact vials should be stored at controlled room temperature.<sup>2951</sup> Stability is not affected by exposure to normal room fluorescent light.<sup>1374</sup>

Plastic devices composed of acrylic or a polymer of acrylonitrile, butadiene, and styrene (ABS) may crack and leak when used with undiluted etoposide.<sup>2951</sup> In one study, a multiport disposable infusion cassette (Omni-Flow) developed cracks within 5 minutes after infusion was started and leakage was evident within 15 minutes. This phenomenon did not occur when etoposide was diluted to concentrations up to 1 mg/mL. In addition, a venting pin and a connector on an extension set reportedly

cracked. Exposure to the polyethylene glycol 300 content of the etoposide formulation can cause cracks in minutes. However, dehydrated alcohol did not cause any cracks within 1 hour.<sup>1261</sup>

Immersion of a needle with an aluminum component in etoposide (Bristol) 20 mg/mL resulted in no visually apparent reaction after 7 days at 24°C.<sup>988</sup>

### Precipitation

Dextrose 5% and sodium chloride 0.9% have been recommended as diluents for the infusion of etoposide.<sup>2951</sup> Unlike etoposide phosphate, the aqueous solubility of etoposide is poor (0.03 mg/mL), but the formulation temporarily increases its miscibility in an aqueous medium. Nevertheless, the drug will eventually crystallize in varying time periods, and the crystallization is reported to be exacerbated by peristaltic pumps.<sup>1949</sup> At concentrations of 0.2 and 0.4 mg/mL in dextrose 5% or sodium chloride 0.9%, the solutions are stable for 96 and 24 hours, respectively, at 25°C under normal fluorescent light in either glass or plastic containers.<sup>2951</sup> However, precipitation in shorter time periods has been observed. At concentrations of 0.2 and 0.4 mg/mL in Ringer's injection, lactated, or mannitol 10% in glass containers under the same conditions, the solutions are stable for 8 hours. No precipitate formed in 72 hours at 20°C in solutions of etoposide 0.4 mg/mL in dextrose 5% in sodium chloride 0.45%.<sup>1162</sup> However, at 1 mg/mL, crystallization may occur in 30 minutes in a standing solution or 5 minutes if the solution is stirred. Occasionally, 1-mg/mL concentrations may remain in solution for extended periods.<sup>1374</sup> Nevertheless, concentrations greater than 0.4 mg/mL are not recommended by the manufacturer.<sup>2951</sup> Because of the poor solubility of etoposide in aqueous media, monitor closely for precipitation before and during administration.<sup>915 916</sup>

The rate of precipitation of a supersaturated etoposide solution depends on the presence of crystalline nuclei, agitation, contact with incompatible surfaces, and possibly other factors.<sup>1374</sup>

Etoposide 1 mg/mL in sodium chloride 0.9% in polypropylene syringes (Braun Omnifix) developed a pure etoposide precipitate in about 10% of the prefilled syringes. It also precipitated at various locations in subclavian lines.<sup>1564</sup>

Precipitation of etoposide from infusion solutions is reportedly exacerbated by the use of peristaltic pumps, especially at concentrations of 0.4 mg/mL or above. Use of volumetric pumps has been recommended to reduce this problem.<sup>1832 1949</sup>

### pH Effects

Etoposide is most stable at a pH of about 3.5 to 6, with a calculated minimum degradation rate occurring at pH 4.8.<sup>1262</sup> Epimerization to the less active *cis*-etoposide may occur at pH values above 6. Hydrolysis may occur in alkaline solutions.<sup>1379</sup>

## Syringes

When etoposide 1 mg/mL in sodium chloride 0.9% was stored in plastic syringes (Gillette), seizing of the syringes occurred.<sup>1564</sup>

## Ambulatory Pumps

Etoposide (Bristol-Myers Squibb) 0.5 mg/mL in sterile water for injection was evaluated for stability and compatibility in polyvinyl chloride (PVC) reservoirs of Graseby 9000 ambulatory pumps. Etoposide was chemically stable at 37°C for 7 days with no loss of drug. However, refrigerated storage at 4°C resulted in precipitation of the etoposide in some samples. In addition, substantial amounts of diethylhexyl phthalate (DEHP) plasticizer (up to 90 mcg/mL) were leached from the PVC reservoirs. The authors concluded that etoposide was unsuitable for use in this pump reservoir and recommended consideration of etoposide phosphate, which should not be subject to precipitation and leaching of plasticizer.<sup>2288</sup>

## Sorption

No loss of etoposide because of sorption to PVC containers has been observed.<sup>1374</sup>

In an admixture composed of cytarabine (Upjohn) 0.157 mg/mL, daunorubicin hydrochloride (Bellon) 15.7 mcg/mL, and etoposide (Sandoz) 0.157 mg/mL in dextrose 5%, little or no loss of the drugs due to sorption occurred when delivered through PVC, PVC with polyethylene-lined sets, and silicone central catheter.<sup>1955</sup>

## Plasticizer Leaching

The surfactant in the etoposide formulation leaches DEHP plasticizer from PVC containers and tubing. The amount of DEHP leached is variable, depending on surfactant concentration, container size, tubing diameter and length, ambient temperature, DEHP concentration in the plastic, and contact time. The use of non-PVC containers and tubing has been recommended to reduce patient exposure to DEHP. If there is sufficient concern, the use of the water-soluble ester form, etoposide phosphate, which does not leach DEHP plasticizer, could be used.

Etoposide 0.4 mg/mL in PVC bags of dextrose 5% leached relatively minor amounts of DEHP plasticizer from PVC bags. This leaching was due to the surfactant polysorbate 80 (Tween 80) in the formulation. After 24 hours at 24°C, the DEHP concentration in 50-mL bags of infusion solution was 2.6 mcg/mL. This finding is consistent with the low surfactant concentration

(0.16%) in the final admixture solution. The actual amount of DEHP leached from PVC containers and administration sets may vary in clinical situations, depending on surfactant concentration, bag size, and contact time.<sup>1683</sup>

Etoposide (Sandoz) 0.4 mg/mL in sodium chloride 0.9% in PVC containers leached DEHP plasticizer from the container material. This leaching increased with storage time from about 12 mcg/mL in 8 hours to over 50 mcg/mL in 96 hours at 24°C. Refrigeration reduced, but did not eliminate, DEHP leaching.<sup>1833</sup>

Etoposide (Novartis) 0.4 mg/mL in dextrose 5% and sodium chloride 0.9% was evaluated for the leaching of DEHP plasticizer from PVC bags of the infusion solution from 4 manufacturers (Aguettant, Baxter, Biosedra-Fresenius, and Macopharma) over 24 hours stored at 24°C. Both solutions from all manufacturers leached DEHP in amounts near 20 mcg/mL.<sup>2447</sup>

The low-density polyethylene inner linings of trilayer Vygon tubing and bilayer Cair tubing have been reported not to act as effective barriers to DEHP leaching from the outer PVC layers. Leached DEHP was nearly identical to plain PVC tubing.<sup>2587 2605</sup>

## Filtration

Etoposide 0.1 to 0.4 mg/mL in dextrose 5% or sodium chloride 0.9% has been filtered through several commercially available filters (such as the 0.22- $\mu$ m Millex-GS or Millex GV) without filter decomposition.<sup>4</sup>

Etoposide (Sandoz) 0.2 mg/mL in dextrose 5% and sodium chloride 0.9% was filtered through a 0.22- $\mu$ m cellulose ester membrane filter (Ivex-HP, Millipore) over 6 hours. No significant drug loss due to binding to the filter was noted.<sup>1034</sup>

## Central Venous Catheter

Etoposide infused undiluted at a rate of 30 mL/hr for 24 hours through a polyurethane central catheter caused substantial damage to the catheter. In addition to cracking the catheter, a 36% decrease in elasticity, a 3.7% increase in catheter length, and damage similar to melting on the internal catheter wall were found. The damage also occurred with the etoposide vehicle and ethanol alone. Consequently, the damage was attributed to the ethanol component of the formulation.<sup>2286</sup>

The damage to polyurethane catheters caused by the etoposide formulation did not extend to silicone central catheters. Administration of undiluted etoposide could be performed using silicone catheters.<sup>2286</sup>

## AHFS 10:00

### Products

Etoposide phosphate is available in single-dose vials containing the equivalent of 100 mg of etoposide as the phosphate along with sodium citrate 32.7 mg and 300 mg of dextran 40. Reconstitute with 5 or 10 mL of compatible diluent to yield solutions of 20 or 10 mg/mL, respectively. Sterile water for injection, dextrose 5%, sodium chloride 0.9%, bacteriostatic water for injection preserved with benzyl alcohol, or bacteriostatic sodium chloride 0.9% preserved with benzyl alcohol may be used for reconstitution.<sup>1(6/07)</sup>

### pH

Reconstitution with sterile water for injection to a concentration of 1 mg/mL results in a pH of approximately 2.9.<sup>4</sup>

### Trade Name(s)

Etopophos

### Administration

Etoposide phosphate is administered by intravenous infusion from 5 to 210 minutes. The reconstituted drug may be given without further dilution or may be diluted to a concentration as low as 0.1 mg/mL with dextrose 5% or sodium chloride 0.9%.<sup>1(6/07) 4</sup>

### Stability

Etoposide phosphate is a white to off-white powder.<sup>4</sup> Intact vials should be stored under refrigeration at 2 to 8°C and protected from light.<sup>1(6/07)</sup>

The manufacturer states that etoposide phosphate reconstituted with an unpreserved diluent (such as sterile water for injection, dextrose 5%, or sodium chloride 0.9%) is stable for 24 hours at room temperatures of 20 to 25°C and 7 days under refrigeration at 2 to 8°C. If a diluent containing benzyl alcohol as a preservative (such as bacteriostatic water for injection or bacteriostatic sodium chloride 0.9%) is used to reconstitute etoposide phosphate, the solution is stable for 48 hours at room temperatures of 20 to 25°C and for 7 days under refrigeration at 2 to 8°C.<sup>1(6/07) 4</sup>

Unlike etoposide, the phosphate ester is highly water soluble, having a solubility over 100 mg/mL.<sup>4</sup> Consequently, the potential for precipitation in aqueous media is reduced greatly compared with the older surfactant- and organic solvent-based formulation.<sup>2219</sup>

Etoposide production by hydrolysis from infusion admixtures of etoposide phosphate (Bristol-Myers Squibb) was measured. The admixtures, equivalent to etoposide 1.5 mg/mL in 66.7 mL and 15 mg/mL in 20 mL of sodium chloride 0.9%, were filled into polyvinyl chloride (PVC) ambulatory infusion pump reservoirs (Pharmacia Deltec) and stored at 20 and 37°C protected from light. Etoposide levels in the etoposide phosphate admixtures increased at both temperatures; in 7 days the increase in concentration was about 2% at 20°C and about 7% at 37°C. The authors concluded that etoposide phosphate is suitable for multiple-day ambulatory infusion.<sup>2024</sup>

Doxorubicin hydrochloride, etoposide phosphate, and vincristine sulfate admixtures at a variety of concentrations were unable to pass the USP test for antimicrobial effectiveness. Mixtures of these drugs are not "self-preserving" and permit microbial growth.<sup>2343</sup>

Etoposide phosphate (Bristol Myers Squibb) 0.09 mg/mL in sodium chloride 0.9% did not result in the loss of viability of *Staphylococcus aureus*, *Enterococcus faecium*, *Pseudomonas aeruginosa*, and *Candida albicans* within 120 hours at 22°C. Diluted solutions should be stored under refrigeration whenever possible, and the potential for microbiological growth should be considered when assigning expiration periods.<sup>2740</sup>

### Light Effects

An evaluation of etoposide phosphate (Bristol-Myers Squibb) 2 mg/mL, doxorubicin hydrochloride 0.4 mg/mL, and vincristine sulfate 0.016 mg/mL (16 mcg/mL) in sodium chloride 0.9% in polyolefin plastic bags (McGaw) found little or no effect of constant exposure to normal fluorescent room light for 124 hours. The admixtures were physically compatible, and all 3 drugs in the admixture remained stable throughout the time stored at an elevated temperature of 35 to 40°C.<sup>2343</sup>

### Syringes

Etoposide phosphate (Bristol Laboratories Oncology Products) 10 and 20 mg/mL was prepared with bacteriostatic water for injection preserved with benzyl alcohol 0.9% (Abbott). The solutions were packaged as 4 mL of solution in 5-mL polypropylene syringes (Becton Dickinson) and sealed with tip caps (Red Cap, Burren Medical). The syringes were stored at 32°C for 7 days, 23°C for 31 days, and 4°C for 31 days. All samples were physically stable, with no visual change and no increase in measured haze or particle content, and little drug loss occurred. At 32°C, 2 to 4% loss occurred in 7 days. At 23°C, about 6 to 7% loss occurred in 31 days. Losses under refrigeration were 4% or less in 31 days.<sup>2219</sup>

## Factor Xa (Recombinant), Inactivated-zhzo

AHFS 20:28.92

Andexanet alfa

### Products

Factor Xa (recombinant), inactivated-zhzo is available in single-use (preservative-free) vials as a lyophilized cake or powder containing 100 or 200 mg of the drug.<sup>3429</sup> Each 100-mg vial also contains tromethamine (TRIS), L-arginine hydrochloride, sucrose 2% (w/v), mannitol 5% (w/v), and polysorbate 80 0.01% (w/v).<sup>3429</sup> Each 200-mg vial also contains tromethamine (TRIS), tromethamine hydrochloride, L-arginine hydrochloride, sucrose 1% (w/v), mannitol 2.5% (w/v), and polysorbate 80 0.01% (w/v).<sup>3429</sup>

Factor Xa (recombinant), inactivated-zhzo is administered as an intravenous bolus infusion, followed by a continuous intravenous infusion.<sup>3429</sup> (See Administration.)

To prepare the bolus dose for intravenous infusion, the total number of vials required should be determined and all vials necessary to achieve the required dose should be reconstituted in succession in order to reduce the total reconstitution time.<sup>3429</sup> Each 100- or 200-mg vial should be reconstituted with 10 or 20 mL, respectively, of sterile water for injection using a 20-mL or larger syringe with a 20-gauge or larger needle to slowly inject the diluent onto the inside wall of the vial to minimize foaming.<sup>3429</sup> Vials should be swirled gently until the contents are completely dissolved, typically for about 3 to 5 minutes each, to yield a 10-mg/mL solution.<sup>3429</sup> Vials should *not* be shaken, because foaming may occur.<sup>3429</sup> The reconstituted solution should be visually inspected for particulate matter and discoloration.<sup>3429</sup> Vials exhibiting incomplete dissolution should be discarded and should not be used.<sup>3429</sup> To prepare the initial intravenous bolus dose for infusion, a 60-mL or larger syringe with a 20-gauge or larger needle should be used to withdraw the appropriate volume of the reconstituted solution from the vials to achieve the dose.<sup>3429</sup> The reconstituted solution should be transferred to an appropriately sized empty 250-mL or smaller polyolefin or polyvinyl chloride (PVC) bag.<sup>3429</sup> Any unused portion of the reconstituted solution should be discarded.<sup>3429</sup>

To prepare the continuous intravenous infusion, the same procedure should be followed as that used to prepare the bolus infusion dose; however, multiple 40- to 60-mL syringes or an

equivalent 100-mL syringe may be used to withdraw the appropriate volume of the reconstituted solution from the vials to achieve the dose.<sup>3429</sup>

### Trade Name(s)

Andexxa

### Administration

Factor Xa (recombinant), inactivated-zhzo is administered intravenously only.<sup>3429</sup> The reconstituted solution should be infused through a 0.2- or 0.22- $\mu$ m polyethersulfone or equivalent low protein-binding inline filter.<sup>3429</sup>

An initial intravenous bolus dose should be infused, beginning at a target rate of approximately 30 mg/min.<sup>3429</sup>

Within 2 minutes of completing infusion of the bolus dose, a continuous intravenous infusion should be started and administered at a rate of 4 or 8 mg/min, depending on the dosing regimen used, for up to 120 minutes.<sup>3429</sup>

### Stability

Factor Xa (recombinant), inactivated-zhzo is a white to off-white cake or powder that forms a clear, colorless to slightly yellow solution upon reconstitution.<sup>3429</sup> Intact vials should be stored under refrigeration at 2 to 8°C; vials should *not* be frozen.<sup>3429</sup>

The reconstituted solution is stable *in vials* for up to 8 hours at room temperature or may be stored for up to 24 hours at 2 to 8°C.<sup>3429</sup> The reconstituted solution *in the listed plastic intravenous infusion bags* is stable for up to 8 hours at room temperature.<sup>3429</sup>

### Sorption

The manufacturer recommends the use of polyolefin or PVC intravenous infusion bags in the preparation of the drug for bolus and continuous intravenous infusions.<sup>3429</sup>

### Filtration

The reconstituted solution for infusion should be administered through a 0.2- or 0.22- $\mu$ m polyethersulfone or equivalent low protein-binding inline filter.<sup>3429</sup>

## Famotidine

AHFS 56:28.12

### Products

Famotidine is available as a 10-mg/mL concentrated injection in 2-mL single-dose vials and 4- and 20-mL multiple-dose vials. Each mL of the solution also contains L-aspartic acid 4 mg and mannitol 20 mg. Benzyl alcohol 0.9% is present as a preservative in the multiple-dose product.<sup>1(10/06)</sup>

Famotidine is also available premixed at a concentration of 20 mg/50 mL. Each 50 mL of solution also contains L-aspartic acid 6.8 mg and sodium chloride 450 mg in water for injection. Additional L-aspartic acid or sodium hydroxide may be added to adjust the pH.<sup>1(10/06)</sup>

### pH

The injection has a pH from 5 to 5.6.<sup>4</sup> The premixed solution has a pH from 5.7 to 6.4.<sup>1(10/06)</sup>

### Osmolarity

The osmolarities of the single- and multiple-dose products are 217 and 290 mOsm/L, respectively.<sup>4</sup>

### Sodium Content

Famotidine premixed infusion solution has 7.8 mEq of sodium per 50 mL.<sup>4</sup>

### Trade Name(s)

Pepcid

### Administration

Famotidine is administered by slow intravenous injection or infusion. For injection, 20 mg should be diluted to 5 to 10 mL with a compatible diluent and injected no faster than 10 mg/min. For infusion, 20 mg should be diluted in 100 mL of dextrose 5% or another compatible diluent and infused over 15 to 30 minutes. Alternatively, famotidine premixed solution may be administered by intravenous infusion over 15 to 30 minutes.<sup>1(10/06)</sup><sup>4</sup>

### Stability

Famotidine injection is a clear, colorless solution. The vials should be stored under refrigeration and protected from freezing.

If freezing occurs, thaw at room temperature; make sure that all components have resolubilized.<sup>1(10/06)</sup><sup>4</sup> Use of a microwave oven for thawing is not recommended because of the potential hazard of vapor pressure increases in the vials.<sup>4</sup>

Although refrigeration is recommended, the manufacturer has indicated that the drug may be stored at room temperature for 26 weeks<sup>1239</sup> and for 3 months<sup>2745</sup> at controlled room temperature in differing statements.

Famotidine premixed infusion solution should be stored at controlled room temperature (25°C) and protected from excessive heat. Brief exposure to temperatures up to 35°C does not affect the stability of the product adversely.<sup>1(10/06)</sup>

### Freezing Solutions

Famotidine (MSD) 200 mcg/mL in dextrose 5% or sodium chloride 0.9% in polyvinyl chloride (PVC) bags showed no loss when frozen at -20°C for 28 days followed by storage at 4°C for 14 days.<sup>1271</sup>

Famotidine (MSD) 2 mg/mL in dextrose 5%, sodium chloride 0.9%, or sterile water for injection stored in polypropylene syringes (Becton Dickinson) exhibited a 5 to 8% loss in 8 weeks when frozen at -20°C.<sup>1486</sup>

### Syringes

Famotidine (MSD) 2 mg/mL in dextrose 5%, sodium chloride 0.9%, or sterile water for injection stored in plastic syringes (Becton Dickinson) exhibited no loss in 14 days at 4°C.<sup>1487</sup>

### Central Venous Catheter

Famotidine (Merck) 2 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Fat Emulsion, Intravenous

### AHFS 40:20

#### Products

The compositions and characteristics of fat emulsion, intravenous, products are listed in Table 1.

In addition, fat emulsion, intravenous (as Intralipid 20%), is available as one component of 3-chamber bag products that also contain amino acids with electrolytes and dextrose in a fixed volume and concentration (i.e., Kabiven and Perikabiven, both by Fresenius Kabi).<sup>3264 3265</sup> The specific product labeling should be consulted for additional details on the formulation, administration, and stability of these products.<sup>3264 3265</sup>

#### pH

The pH of fat emulsion, intravenous, products is adjusted with sodium hydroxide to a pH ranging from 6 to 8.9<sup>3251 3252 3253 3254</sup> or 9.<sup>3255 3444</sup>

#### Osmolality

The osmolality of Intralipid 30% is approximately 310 mOsm/kg.<sup>3253</sup>

The osmolality of Omegaven 10% is approximately 342 mOsm/kg.<sup>3444</sup>

The osmolality of Intralipid 20% is approximately 350 mOsm/kg.<sup>3251 3252</sup>

The osmolality of Smoflipid 20% is approximately 380 mOsm/kg.<sup>3255</sup>

The osmolality of Nutrilipid 20% is 390 mOsm/kg.<sup>3254</sup>

#### Osmolarity

The osmolarity of Intralipid 30% is 200 mOsm/L.<sup>3253</sup>

The osmolarity of Intralipid 20% is 260 mOsm/L.<sup>3251 3252</sup>

The osmolarity of Smoflipid 20% is 270 mOsm/L.<sup>3255</sup>

The osmolarity of Omegaven 10% is 273 mOsm/L.<sup>3444</sup>

The osmolarity of Nutrilipid 20% is 290 mOsm/L.<sup>3257</sup>

#### Phosphate Content

The phosphate content of Smoflipid 20% and Omegaven 10% is 15 mmol/L.<sup>3255 3444</sup>

#### Aluminum Content

Fat emulsion, intravenous, products contain no more than 25 mcg of aluminum per L.<sup>3251 3252 3253 3254 3255 3444</sup>

#### Trade Name(s)

Intralipid, Nutrilipid, Omegaven, Smoflipid

#### Administration

Fat emulsion, intravenous 10 and 20%, may be administered alone by intravenous infusion via a peripheral or central vein.<sup>3251 3254 3255 3444</sup> Fat emulsion, intravenous, also may be administered

by intravenous infusion in total nutrient admixtures (TNA, "3-in-1") in combination with amino acids, dextrose, and other nutrients; however, selection of the peripheral or central venous route depends upon the osmolality of the final infusate.<sup>3251 3252 3253 3254 3255 3444</sup> Some manufacturers state that solutions with an osmolality of 900 mOsm/L or more must be infused through a central vein.<sup>3255 3444</sup>

Fat emulsion, intravenous, in pharmacy bulk packages is used as a component in parenteral nutrition admixtures; fat emulsion, intravenous, in pharmacy bulk packages is *not* intended for direct intravenous administration.<sup>3252 3253 3254</sup>

The specific product labeling should be consulted for additional details on initial infusion rates, titration, and maximum infusion rates in various populations.<sup>3251 3252 3253 3254 3255 3444</sup>

#### Stability

Fat emulsion, intravenous, products may be stored in the intact containers at controlled room temperature<sup>3255</sup> or at temperatures of 25°C or less; the specific manufacturer's instructions should be consulted.<sup>3251 3252 3253 3254 3444</sup> The emulsions should be protected from freezing; any product that has been frozen should be discarded.<sup>3251 3252 3253 3254 3255 3444</sup> Excessive heat also should be avoided.<sup>3255 3444</sup>

In general, admixtures containing fat emulsion, intravenous, should be used immediately after preparation, but may be stored for up to 24 hours under refrigeration at 2 to 8°C; admixtures should be infused within 24 hours after removal from such storage at 2 to 8°C.<sup>3251 3252 3253 3254 3255 3444</sup> The specific product labeling should be consulted for additional details on stability of admixtures. If pharmacy bulk packages of fat emulsion, intravenous, are used to prepare such admixtures, the contents of the pharmacy bulk package should be transferred to a suitable admixture container as soon as possible within 4 hours after the bulk package closure has been penetrated.<sup>3252 3253 3254</sup>

Excessive acidity (e.g., pH less than 5) and inappropriate electrolyte content are the primary destabilizers of emulsions.<sup>3251 3252 3253 3254 3255 3444</sup> A 2-year study of Intralipid 10% found an increase in free fatty acids and a decrease in pH on storage. Gross particles formed and toxicity to rabbits increased with time. These changes were greatest during storage at 40°C but were measurable at 20 and even 4°C. The toxicity of the emulsions to rabbits could be correlated to the extent of free fatty acid formation in the emulsions. The formation of free fatty acids, with a consequent lowering of pH, is the major route of degradation of fat emulsions. The rate of degradation is minimized at pH 6 to 7.<sup>889</sup>

The container-closure system is important for long-term stability. Plastic containers are generally permeable to oxygen, which can readily oxidize the lipid emulsions, so glass bottles

**Table 1. Composition and characteristics of several fat emulsion, intravenous, products**

Component or Characteristic	Intralipid 20% (Baxter) <sup>3251 3252</sup>	Intralipid 30% (Baxter) <sup>3253</sup>	Nutrilipid 20% (B. Braun) <sup>3254</sup>	Smoflipid 20% (Fresenius Kabi) <sup>3255 3258</sup>	Omegaven 10% (Fresenius Kabi) <sup>3444</sup>

<sup>a</sup> Not for direct infusion.

<sup>b</sup> Must be combined with dextrose and amino acid solutions such that the final concentration of fat in the total nutrient admixture (TNA) does not exceed 20%.

have been used. Furthermore, the stoppers must not be permeable to oxygen and must not soften on contact with the emulsions. Teflon-coated stoppers have been recommended. Finally, the emulsions are packed under an atmosphere of nitrogen.<sup>889 3420 3421 3422</sup> More recently, specifically designed lipid-compatible plastic (e.g., polypropylene) containers made of multilayered film have been used.<sup>3251 3252 3253</sup>

The long-term room temperature stability of the emulsions is lost when the intact containers are entered. The integrity of

the nitrogen layer in the sealed container is essential for room temperature stability. Exposure of Intralipid 10% to the atmosphere has resulted in gradual changes in the emulsion system. No changes in the particle size distribution occurred during the first 36 hours of room temperature storage. After 48 hours at room temperature, globule coalescence was noticeable. By 72 hours, the changes had become significant; however, the visual appearance after 72 hours was unchanged. Long-term storage for 15 months at room temperature resulted in formation of a

nonhomogeneous cream layer with oil globules on top.<sup>656 657</sup> If the pH of the emulsion is optimal and the emulsion is stored under nitrogen and not exposed to direct sunlight, oxidative degradation is not likely to be significant.<sup>889</sup>

The manufacturers state that partially used containers should be discarded<sup>3254 3255 3444</sup> and that no container should be used if the emulsion appears to be oiling out.<sup>3251 3252 3253 3255 3444</sup>

Fat emulsion, intravenous, has been shown to support the growth of various microbes, including both bacterial and fungal species. No visual changes occurred in the emulsions to suggest contamination.<sup>1102 1103 1104 1216</sup> The potential for microbiological growth should be considered when assigning expiration periods.

The 3-in-1 parenteral nutrition solutions that have a lower pH and higher osmolality due to the presence of amino acids and dextrose reportedly do not support microbial growth as well as fat emulsion alone;<sup>1216</sup> however, this risk still exists and the use of strict aseptic technique in the preparation of such admixtures is essential.<sup>3251 3252 3253 3254 3255 3444</sup>

See Additional Compatibility Information for other information on stability of fat emulsion, intravenous, including stability of multicomponent (3-in-1) admixtures.

### Freezing Emulsions

Freezing may cause physical damage. The emulsions may become coarse and coalesce, and they can undergo irreversible phase separation.<sup>559</sup>

The emulsions should *not* be frozen.<sup>3251 3252 3253 3254 3255 3444</sup> If accidental freezing occurs, the products should be discarded.<sup>3251 3252 3253 3254 3255 3444</sup>

### Syringes

The physical stability of fat emulsion, intravenous (ClinOleic 20%, Baxter; Intralipid 20%, Fresenius Kabi; Lipofundin MCT/LCT, Braun; Omegaven 10%, Fresenius Kabi; Smoflipid, Fresenius Kabi) packaged as 20 mL in 20-mL polypropylene syringe (Becton Dickinson) was evaluated at 4°C, 25°C with 60% relative humidity, and 40°C with 75% relative humidity.<sup>3457 3458</sup> Visual and microscopic observations, pH analysis, measurement of oil droplet size (via laser diffraction and photon correlation spectroscopy methods), and zeta potential analysis were performed.<sup>3457</sup> The author concluded that the emulsions were physically stable for 30 days at 4 and 25°C and for 21 days at 40°C.<sup>3457</sup>

### Plasticizer Leaching

Diethylhexyl phthalate (DEHP)-containing devices (e.g., containers, administration sets, lines) should *not* be used for the administration of fat emulsion, intravenous.<sup>3251 3252 3253 3254 3255 3259 3444</sup> Fat emulsion extracts DEHP plasticizer from polyvinyl

chloride (PVC) equipment.<sup>3251 3252 3253</sup> The amount of plasticizer leached from PVC sets by fat emulsion is directly related to the length of administration time and inversely related to the flow rate; these two factors influence the amount of contact time between the fat emulsion and the PVC tubing. Longer administration times and slower administration rates increase the amount of leached plasticizer. Non-PVC plastic containers, such as an ethylene vinyl acetate (EVA) bag, may be used to avoid plasticizer exposure.<sup>658 661 673 893 1105</sup>

Storage of Intralipid 10 and 20% for 24 hours in PVC sets resulted in phthalate contents of 64 to 70 mcg/mL at 5°C and 144 to 160 mcg/mL at ambient temperature. When the fat emulsions were simply infused through PVC sets, phthalate content dropped to 3.6 to 8.5 mcg/mL. A patient being administered 500 mL of fat emulsion per day would receive about 1.5 to 2.75 mg of phthalate per day. Negligible levels of phthalate were delivered from a parenteral nutrition admixture containing fat emulsion.<sup>1264</sup>

A parenteral nutrition solution containing an amino acid solution, dextrose, and electrolytes in a PVC bag did not leach measurable quantities of DEHP plasticizer during 21 days of storage at 4 and 25°C. However, addition of fat emulsion 10 or 20% to the formula caused detectable leaching of DEHP from the PVC containers stored for 48 hours. Higher DEHP levels were found in the 25°C samples than in the 4°C samples. The authors recommended limiting the use of lipid-containing parenteral nutrition admixtures to 24 to 36 hours. Use of non-PVC containers and tubing is another option.<sup>1430</sup>

Total nutrient admixtures with fat emulsion concentrations ranging from 1 to 3.85% were found to leach DEHP plasticizer even though they were packaged in EVA bags. The bags had PVC sites in their composition, which contributed the DEHP. Use of PVC administration sets added additional DEHP. Leached DEHP ranged from about 200 mcg to 2 mg during simulated infusions conducted immediately after preparation. The authors concluded that children who are treated regularly with TNA are exposed to significant amounts of DEHP.<sup>2588</sup>

### Filtration

A 1.2- $\mu$ m inline filter should be used in the administration of fat emulsion, intravenous, when used alone and when administered as a component of a 3-in-1 admixture (TNA), to reduce the potential for patient harm due to particulates, microprecipitates, and air emboli.<sup>3251 3252 3253 3254 3255 3259 3260 3444</sup>

*Only* a 1.2- $\mu$ m filter should be used; filters with a pore size smaller than 1.2- $\mu$ m must not be used with lipid emulsions.<sup>3251 3252 3253</sup> The particle size of the fat emulsion products may exceed the porosity of some inline filters, and such small porosity filters should not be used with fat emulsion products.<sup>658 1106</sup>

## Compatibility Information

### Solution Compatibility

#### Fat emulsion, intravenous

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Amino acids 8.5%	MG	VT	10%	Mixed in equal parts. Physically compatible for 48 hr at 4°C and room temperature	32	C

Ampicillin sodium		20 g		10%		15% ampicillin loss in 24 hr at 23°C	37	I

**Additive Compatibility (Cont.)**

Test Drug	Mfr	Conc/L or %	Mfr	Conc/L or %	Test Solution	Remarks	Ref	C/I
Ampicillin sodium	BE	2 g	VT	10%		Lipid coalescence in 24 hr at 25 and 8°C	825	I
Ascorbic acid	VI	1 g	VT	10%		Physically compatible for 48 hr at 4°C and room temperature	32	C
Ascorbic acid	DB	500 mg	VT	10%		Lipid coalescence in 24 hr at 25 and 8°C	825	I
Calcium chloride		1 g	CU	10%		Immediate flocculation with visually apparent layer in 2 hr at room temperature	656	I
Calcium chloride		500 mg	CU	10%		Flocculation within 4 hr at room temperature	656	I
Calcium chloride	DB	1 g	VT	10%		Coalescence and creaming in 8 hr at 8 and 25°C	825	I
Calcium chloride		10 and 20 mEq	KV	10%		Immediate flocculation, aggregation, and creaming	1018	I
Calcium gluconate	PR	2 g	CU	10%		Produced cracked emulsion	32	I
Calcium gluconate		7.2 and 9.6 mEq	KV	10%		Immediate flocculation, aggregation, and creaming	1018	I
Chloramphenicol sodium succinate	PD	2 g	VT	10%		Physically compatible for 48 hr at 4°C and room temperature	32	C
Chloramphenicol sodium succinate	PD	2 g	VT	10%		Physically compatible for 24 hr at 8 and 25°C	825	C
Cloxacillin sodium		10 g		10%		Aggregation of oil droplets	37	I
Cyclosporine	SZ	400 mg	AB	10%		No cyclosporine loss in 72 hr at 21°C	1616	C
Cyclosporine	SZ	500 mg and 2 g	KA	10 and 20%		Physically compatible with no cyclosporine loss in 48 hr at 24°C under fluorescent light	1625	C
Diphenhydramine HCl	PD	200 mg	VT	10%		Physically compatible for 48 hr at 4°C and room temperature	32	C
Famotidine	MSD	20 mg		10%		Little or no famotidine loss in 48 hr at 25°C in light or dark and at 5°C	1344	C
Folic acid	USP	20 and 0.2 mg	KV	10%		Physically compatible for 2 weeks at 4°C and room temperature in the dark but erratic assays	895	?
Fusidate sodium	LEO	1 g		10%		Physically incompatible	1800	I
Gentamicin sulfate	RS	160 mg	VT	10%		Lipid coalescence in 24 hr at 8 and 25°C	825	I
Hydrocortisone sodium succinate	GL	200 mg	VT	10%		Physically compatible for 24 hr at 8 and 25°C	825	C
Multivitamins	USV	4 mL	VT	10%		Physically compatible for 48 hr at 4°C and room temperature	32	C
Multivitamins	KA		KA	10%		Physically compatible for 24 hr at 26°C. Little loss of most vitamins; up to 52% ascorbate loss	2050	C
Octreotide acetate	SZ	1.5 mg	KV	10%		Octreotide content unstable	1373	I
Phenytoin sodium	PD	1 g	VT	10%		Phenytoin crystal precipitation	32	I
Potassium chloride		100 mEq	VT	10%		Physically compatible for 48 hr at 4°C and room temperature	32	C
Potassium chloride		100 mEq	CU	10%		No change in 24 hr at room temperature, but lipid coalescence in 48 hr	656	C

**Additive Compatibility (Cont.)**

Test Drug	Mfr	Conc/L or %	Mfr	Conc/L or %	Test Solution	Remarks	Ref	C/I
Potassium chloride		200 mEq	CU	10%		Coalescence with surface creaming in 4 hr at room temperature. Oil globules on surface at 48 hr	656	I
Potassium chloride	DB	4 g	VT	10%		Lipid coalescence in 24 hr at 8 and 25°C	825	I
Ranitidine HCl	GL	50 and 100 mg	KV	10%		Physically compatible. 4% or less ranitidine loss in 48 hr at 25°C in light or dark	1360	C
Sodium bicarbonate	BR	7.5 g	VT	10%		Physically compatible for 48 hr at 4°C and room temperature	32	C
Sodium bicarbonate		3.4 g	VT	10%		Lipid coalescence in 24 hr at 8 and 25°C	825	I
Sodium chloride		100 mEq	CU	10%		No change for 24 hr at room temperature, but lipid coalescence in 48 hr	656	C
Sodium chloride		200 mEq	CU	10%		Lipid coalescence with surface creaming in 4 hr at room temperature. Oil globules on surface at 48 hr	656	I

<sup>a</sup> Tested in glass containers.

<sup>b</sup> Diluted in dextrose 5% before adding to the fat emulsion.

## Additional Compatibility Information

### Calcium and Phosphate

#### UNRECOGNIZED CALCIUM PHOSPHATE PRECIPITATION IN A 3-IN-1 PARENTERAL NUTRITION MIXTURE RESULTED IN PATIENT DEATH.

The potential for the formation of a calcium phosphate precipitate in parenteral nutrition solutions is well studied and documented,<sup>1771 1777</sup> but the information is complex and difficult to apply to the clinical situation.<sup>1770 1772 1777</sup> The incorporation of fat emulsion in 3-in-1 parenteral nutrition solutions obscures any precipitate that is present, which has led to substantial debate on the dangers associated with 3-in-1 parenteral nutrition mixtures and when or if the danger to the patient is warranted therapeutically.<sup>1770 1771 1772 2031 2032 2033 2034 2035 2036</sup> Because such precipitation may be life-threatening to patients,<sup>2037 2291</sup> FDA issued a Safety Alert containing the following recommendations:<sup>1769</sup>

1. "The amounts of phosphorus and of calcium added to the admixture are critical. The solubility of the added calcium should be calculated from the volume at the time the calcium is added. It should not be based upon the final volume.

Some amino acid injections for TPN admixtures contain phosphate ions (as a phosphoric acid buffer). These phosphate ions and the volume at the time the phosphate is added should be considered when calculating the concentration of phosphate additives. Also, when adding calcium and phosphate to an admixture, the phosphate should be added first.

The line should be flushed between the addition of any potentially incompatible components.

2. A lipid emulsion in a 3-in-1 admixture obscures the presence of a precipitate. Therefore, if a lipid emulsion is needed, either (1) use a 2-in-1 admixture with the lipid infused separately, or (2) if a 3-in-1 admixture is medically necessary, then add the calcium before the lipid emulsion and according to the recommendations in number 1 above.

If the amount of calcium or phosphate which must be added is likely to cause a precipitate, some or all of the calcium should be administered separately. Such separate infusions must be properly diluted and slowly infused to avoid serious adverse events related to the calcium.

3. When using an automated compounding device, the above steps should be considered when programming the device. In addition, automated compounders should be maintained and operated according to the manufacturer's recommendations.

Any printout should be checked against the programmed admixture and weight of components.

4. During the mixing process, pharmacists who mix parenteral nutrition admixtures should periodically agitate the admixture and check for precipitates. Medical or home care personnel who start and monitor these infusions should carefully inspect for the presence of precipitates both before and during infusion. Patients and care givers should be trained to visually inspect for signs of precipitation. They also should be advised to stop the infusion and seek medical assistance if precipitates are noted.
5. A filter should be used when infusing either central or peripheral parenteral nutrition admixtures. At this time, data have

not been submitted to document which size filter is most effective in trapping precipitates.

Standards of practice vary, but the following is suggested: a 1.2- $\mu\text{m}$  air-eliminating filter for lipid-containing admixtures and a 0.22- $\mu\text{m}$  air-eliminating filter for non-lipid-containing admixtures.

6. Parenteral nutrition admixtures should be administered within the following time frames: if stored at room temperature, the infusion should be started within 24 hours after mixing; if stored at refrigerated temperatures, the infusion should be started within 24 hours of rewarming. Because warming parenteral nutrition admixtures may contribute to the formation of precipitates, once administration begins, care should be taken to avoid excessive warming of the admixture.

Persons administering home care parenteral nutrition admixtures may need to deviate from these time frames. Pharmacists who initially prepare these admixtures should check a reserve sample for precipitates over the duration and under the conditions of storage.

7. If symptoms of acute respiratory distress, pulmonary emboli, or interstitial pneumonitis develop, the infusion should be stopped immediately and thoroughly checked for precipitates. Appropriate medical interventions should be instituted. Home care personnel and patients should immediately seek medical assistance."

### Calcium Phosphate Precipitation Fatalities

Fatal cases of paroxysmal respiratory failure in 2 previously healthy women receiving peripheral vein parenteral nutrition were reported. The patients experienced sudden cardiopulmonary arrest consistent with pulmonary emboli. The authors used in vitro simulations and an animal model to conclude that unrecognized calcium phosphate precipitation in a 3-in-1 TNA caused the fatalities. The precipitation resulted during compounding by introducing calcium and phosphate near to one another in the compounding sequence and prior to complete fluid addition. This resulted in a temporarily high concentration of the drugs and precipitation of calcium phosphate. Observation of the precipitate was obscured by the incorporation of 20% fat emulsion, intravenous, into the nutrition mixture. No filter was used during infusion of the fatal nutrition admixtures.<sup>2037</sup>

In a follow-up retrospective review, 5 patients were identified who had respiratory distress associated with the infusion of the 3-in-1 admixtures at around the same time. Four of these 5 patients died, although the cause of death could be definitively determined for only 2.<sup>2291</sup>

### Calcium and Phosphate Conditional Compatibility

Calcium salts are conditionally compatible with phosphates in parenteral nutrition mixtures. The incompatibility is dependent on a solubility and concentration phenomenon and is not entirely predictable. Precipitation may occur during compounding or at some time after compounding is completed.

NOTE: Some amino acid solutions inherently contain calcium and phosphate, which must be considered in any projection of compatibility.

## Dextrose

Dextrose in final concentrations of 5 to 12.5% has been shown to cause a progressive coalescence of the globules in Intralipid 10% due to its alteration of pH from about 7 down to about 3.5 in 48 hours.<sup>656</sup>

## Monovalent Cations

Monovalent cations such as potassium and sodium also cause progressive globule coalescence in Intralipid 10 and 20%, leading to surface creaming.<sup>480 490 656 890</sup> The degree and rate of this effect are dependent on the concentration of the ions. A decreasing degree and rate of coalescence were noted as concentrations of sodium chloride or potassium chloride decreased. At 200 mEq/L, the rate is rapid and the effect is severe. In the range of 100 mEq/L or less, significant effects may not occur for over 24 hours.<sup>490 656</sup>

## Divalent Cations

Divalent cations such as calcium and magnesium cause immediate flocculation, with a nonhomogeneous white granular layer forming at the surface of the Intralipid 10%. This is followed by a substantial, visibly distinct layer, which does not redisperse on shaking.<sup>480 490 656</sup>

The creaming of Intralipid 20% when calcium chloride was admixed in concentrations from 0.25 to 5% was found to be concentration dependent, with maximum creaming occurring with the 5% additive in 30 minutes.<sup>890</sup>

## Multicomponent (3-in-1) Admixtures

Because of the potential benefits in terms of simplicity, efficiency, time, and cost savings, the concept of mixing amino acids, carbohydrates, electrolytes, fat emulsion, and other nutritional components together in the same container has been explored. Within limits, the feasibility of preparing such 3-in-1 parenteral nutrition admixtures has been demonstrated as long as a careful examination of the emulsion mixtures for signs of instability is performed prior to administration.<sup>1813</sup>

However, these 3-in-1 mixtures are very complex and inherently unstable. Emulsion stability is dependent on both zeta potential and van der Waals forces, influenced by the presence of dextrose.<sup>2029</sup> Because the ultimate stability of each mixture is the result of various complicated factors, a definitive prediction of stability is impossible. Death and injury have resulted from administration of unrecognized precipitates in 3-in-1 parenteral nutrition admixtures. In addition, the use of 3-in-1 admixtures is associated with a higher rate of catheter occlusion and reduced catheter life compared with giving the fat emulsion separately from the parenteral nutrition solution.<sup>705 1518 2194</sup>

Intravenous administration of unstable fat emulsion with a large amount of large fat globules greater than 5 µm is potentially embolic and has been demonstrated to result in liver toxicity.<sup>2690</sup>

The use of a 5-µm inline filter for a 3-in-1 admixture (containing Travasol 8.5%, dextrose, Intralipid 10%, various electrolytes, vitamins, and trace elements) showed that fat, in the form of large globules or aggregates, comprised 99.4% of

the filter contents. These authors recommended the use of an appropriate filter for preventing catheter occlusion with 3-in-1 admixtures.<sup>742</sup>

The presence of glass particles, talc, and plastic has been observed in administration line samples drawn from 20 adults receiving 3-in-1 parenteral nutrition admixtures and in 20 children receiving 2-in-1 admixtures with separate fat emulsion infusions. Particles ranged from 3 to 5 µm to greater than 40 µm and were more consistently seen in the pediatric admixtures. The authors suggested the use of inline filters given that particulate contamination is present, has no therapeutic value, and can be harmful.<sup>2458</sup>

Combining an amino acids–dextrose parenteral nutrition solution containing various electrolytes with fat emulsion 20%, intravenous (Intralipid, Vitrum), resulted in a mixture that was apparently stable for a limited time. However, it ultimately exhibited a creaming phenomenon. Within 12 hours, a distinct 2-cm layer separated on the upper surface. Aggregates believed to be clumps of fat droplets were found. Fewer and smaller aggregates were noted in the lower layer.<sup>560 561</sup>

Amino acids have been reported to have no adverse effect on the emulsion stability of Intralipid 10%. In addition, the amino acids appeared to prevent the adverse impact of dextrose and to slow the coalescence and flocculation resulting from mono- and divalent cations. However, significant coalescence did result after a somewhat longer time. Therefore, it was recommended that such cations not be mixed with fat emulsion, intravenous.<sup>656</sup>

Three-in-one TNA admixtures prepared with Intralipid 20% and containing mono- and divalent ions as well as heparin sodium 5 units/mL were found to undergo changes consistent with instability, including fat particle shape and diameter changes as well as creaming and layering. The changes were evident within 48 hours at room temperature but were delayed to between 1 and 2 months when refrigerated.<sup>58</sup>

Travenol stated that 1:1:1 mixtures of amino acids 5.5, 8.5, or 10% (Travenol), fat emulsion 10 or 20% (Travenol), and dextrose 10 to 70% are physically stable but recommended administration within 24 hours. M.V.I.-12 3.3 mL/L and electrolytes may also be added to the admixtures up to the maximum amounts listed below:<sup>850</sup>

Calcium	8.3 mEq/L
Magnesium	3.3 mEq/L
Sodium	23.3 mEq/L
Potassium	20 mEq/L
Chloride	23.3 mEq/L
Phosphate	20 mEq/L
Zinc	3.33 mg/L
Copper	1.33 mg/L
Manganese	0.33 mg/L
Chromium	13.33 mcg/L

The stability of mixtures of Intralipid 20% 1 L, Vamin glucose (amino acids with dextrose 10%) 1.5 L, and dextrose 10% 0.5 L with various electrolytes and vitamins was evaluated. Initial emulsion particle size was around 1  $\mu\text{m}$ . The mixture containing only monovalent cations was stable for at least 9 days at 4°C, with little change in particle size. The mixtures containing the divalent cations, such as calcium and magnesium, demonstrated much greater particle size increases, with mean diameters of around 3.3 to 3.5  $\mu\text{m}$  after 9 days at 4°C. After 48 hours of storage, however, these increases were more modest, around 1.5 to 1.85  $\mu\text{m}$ . After storage at 4°C for 48 hours followed by 24 hours at room temperature, very few particles exceeded 5  $\mu\text{m}$ . It was found that the effect of particle aggregation caused by electrolytes demonstrates a critical concentration before the effect begins. For calcium and magnesium chlorides, the critical concentrations were 2.4 and 2.6 mmol/L, respectively. Sodium and potassium chloride had critical concentrations of 110 and 150 mmol/L, respectively. The rate of particle aggregation increased linearly with increasing electrolyte concentration. Heparin 667 units/L had no effect on emulsion stability. The quantity of emulsion in the mixture had a relatively small influence on stability, but higher concentrations exhibited a somewhat greater coalescence.<sup>892</sup>

Instability of the emulsion systems is manifested by (1) flocculation of oil droplets to form aggregates that produce a cream-like layer on top or (2) coalescence of oil droplets leading to an increase in the average droplet size and eventually to a separation of free oil. The lowering of pH and addition of electrolytes can adversely affect the mechanical and electrical properties at the oil-water interface, eventually leading to flocculation and coalescence. Amino acids act as buffering agents and provide a protective effect on emulsion stability. Addition of electrolytes, especially the divalent ions  $\text{Mg}^{++}$  and  $\text{Ca}^{++}$  in excess of 2.5 mmol/L, to simple fat emulsions causes flocculation. But in mixed parenteral nutrition solutions, the stability of the emulsion is enhanced, depending on the quantity and nature of the amino acids present. The authors recommended a careful examination of emulsion mixtures for instability prior to administration.<sup>849</sup>

The stability of an amino acid 4% (Travenol), dextrose 14%, and fat emulsion 4% (Pharmacia) parenteral nutrition solution was reported to be quite good. The solution also contained electrolytes, vitamins, and heparin sodium 4000 units/L. The aqueous solution was prepared first, with the fat emulsion added subsequently. This procedure allowed visual inspection of the aqueous phase and reduced the risk of emulsion breakdown by the divalent cations. Sample mixtures were stored at 18 to 25 and 3 to 8°C for up to 5 days. They were evaluated visually and with a Coulter counter for particle size measurements. Both room temperature and refrigerated mixtures were stable for 48 hours. A marked increase in particle size was noted in the room temperature sample after 72 hours, but refrigeration delayed the changes. The authors' experience with over 1400 mixtures for administration to patients resulted in one emulsion creaming and another cracking. The authors had no explanation for the failure of these particular emulsions.<sup>848</sup>

Six parenteral nutrition solutions having various concentrations of amino acids, dextrose, soybean oil emulsion (Kabi-Vitrum), electrolytes, and multivitamins were reported.

All of the admixtures were stable for 1 week under refrigeration followed by 24 hours at room temperature, with no visible changes, pH changes, or significant particle size changes.<sup>1013</sup> However, other researchers questioned this interpretation of the results.<sup>1014 1015</sup>

The stability of 3-in-1 parenteral nutrition solutions prepared with 500 mL of Intralipid 20%, compared to Soyacal 20%, along with 500 or 1000 mL of FreAmine III 8.5% and 500 mL of dextrose 70% was reported. Also present were relatively large amounts of electrolytes and other additives. All mixtures were similarly stable for 28 days at 4°C followed by 5 days at 21 to 25°C, with little change in the emulsion. A slight white cream layer appeared after 5 days at 4°C, but it was easily dispersed with gentle agitation. The appearance of this cream layer did not statistically affect particle size distribution. The authors concluded that the emulsion mixture remained suitable for clinical use throughout the study period. The stability of other components was not evaluated.<sup>1019</sup>

The stability of 3-in-1 parenteral nutrition admixtures prepared with Liposyn II 10 and 20%, Aminosyn pH 6, and dextrose along with electrolytes, trace metals, and vitamins was reported. Thirty-one different combinations were evaluated. Samples were stored under the following conditions: (1) 25°C for 1 day, (2) 5°C for 2 days followed by 30°C for 1 day, or (3) 5°C for 9 days followed by 25°C for 1 day. In all cases, there was no visual evidence of creaming, free oil droplets, and other signs of emulsion instability. Furthermore, little or no change in the particle size or zeta potential (electrostatic surface charge of lipid particles) was found, indicating emulsion stability. The dextrose and amino acids remained stable over the 10-day storage period. The greatest change of an amino acid occurred with tryptophan, which lost 6% in 10 days. Vitamin stability was not tested.<sup>1025</sup>

The stability of 4 parenteral nutrition admixtures, ranging from 1 L each of amino acids 5.5% (Travenol), dextrose 10%, and fat emulsion 10% (Travenol) up to a "worst case" of 1 L each of amino acids 10% with electrolytes (Travenol), dextrose 70%, and fat emulsion 10% (Travenol) was reported. The admixtures were stored for 48 hours at 5 to 9°C followed by 24 hours at room temperature. There were no visible signs of creaming, flocculation, or free oil. The mean emulsion particle size remained within acceptable limits for all admixtures, and there were no significant changes in glucose, soybean oil, and amino acid concentrations. The authors noted that 2 factors were predominant in determining the stability of such admixtures: electrolyte concentrations and pH.<sup>1065</sup>

Several parenteral nutrition solutions containing amino acids (Travenol), glucose, and lipid, with and without electrolytes and trace elements, produced no visible flocculation or any significant change in mean emulsion particle size during 24 hours at room temperature.<sup>1066</sup>

The compatibility of 10 parenteral nutrition admixtures, evaluated over 96 hours while stored at 20 to 25°C in both glass bottles and EVA bags, was reported. A slight creaming occurred in all admixtures, but this cream layer was easily dispersed by gentle shaking. No fat globules were visually apparent. The mean drop size was larger in the cream layer, but no globules

were larger than 5 µm. Analyses of the concentrations of amino acids, dextrose, and electrolytes showed no changes over the study period. The authors concluded that such parenteral nutrition admixtures can be prepared safely as long as the component concentrations are within the following ranges:<sup>1067</sup>

Vamin glucose or Vamin N (amino acids 7%)	1000 to 2000 mL
Dextrose 10 to 30%	100 to 550 mL
Intralipid 10 or 20%	500 to 1000 mL
Electrolytes (mmol/L)	
Sodium	20 to 70
Potassium	20 to 55
Calcium	2.3 to 2.9
Magnesium	1.1 to 3.1
Phosphorus	0 to 9.2
Chloride	27 to 71
Zinc	0.005 to 0.03

The stability of 8 parenteral nutrition admixtures with various ratios of amino acids, carbohydrates, and fat, consisting of FreAmine III 8.5%, dextrose 70%, and Soyacal 10 and 20% (mixed in ratios of 2:1:1, 1:1:1, 1:1:½, and 1:1:¼, where 1 = 500 mL), was evaluated. Additive concentrations were high to stress the admixtures and represent maximum doses likely to be encountered clinically:

Sodium acetate	150 mEq
Sodium chloride	210 mEq
Potassium acetate	45 mEq
Potassium chloride	90 mEq
Potassium phosphate	15 mM
Calcium gluconate	20 mEq
Magnesium sulfate	36 mEq
Trace elements	present
Folic acid	5 mg
M.V.I.-12	10 mL

The admixtures were stored at 4°C for 14 days followed by 4 days at 22 to 25°C. After 24 hours, all admixtures developed a thin white cream layer, which was readily dispersed by gentle agitation. No free oil droplets were observed. The mean particle diameter remained near the original size of the Soyacal throughout the study. Few particles were larger than 3 µm. Osmolality and pH also remained relatively unchanged.<sup>1068</sup>

Parenteral nutrition 3-in-1 admixtures with Aminosyn and Liposyn have been a problem. Standard admixtures were

prepared using Aminosyn 7% 1000 mL, dextrose 50% 1000 mL, and Liposyn 10% 500 mL. Concentrated admixtures were prepared using Aminosyn 10% 500 mL, dextrose 70% 500 mL, and Liposyn 20% 500 mL. Vitamins and trace elements were added to the admixtures along with the following electrolytes:

Electrolyte	Standard Admixture	Concentrated Admixture
Sodium	125 mEq	75 mEq
Potassium	95 mEq	74 mEq
Magnesium	25 mEq	25 mEq
Calcium	28 mEq	28 mEq
Phosphate	37 mmol	36 mmol
Chloride	83 mEq	50 mEq

Samples of each admixture were (1) stored at 4°C, (2) adjusted to pH 6.6 with sodium bicarbonate and stored at 4°C, or (3) adjusted to pH 6.6 and stored at room temperature. Compatibility was evaluated for 3 weeks.

Signs of emulsion deterioration were visible by 96 hours in the standard admixture and by 48 hours in the concentrated admixture. Clear rings formed at the meniscus, becoming thicker, yellow, and oily over time. Free-floating oil was obvious in 3 weeks in the standard admixture and in 1 week in the concentrated admixture. The samples adjusted to pH 6.6 developed visible deterioration later than the others. The authors indicated that pH may play a greater role than temperature in emulsion stability. However, precipitation (probably calcium phosphate and possibly carbonate) occurred in 36 hours in the pH 6.6 concentrated admixture but not the unadjusted (pH 5.5) samples. Mean particle counts increased for all samples over time but were greatest in the concentrated admixtures. The concentrated admixtures were unsatisfactory for clinical use because of the early increase in particles and precipitation. Furthermore, the standard admixtures should be prepared immediately prior to use.<sup>1069</sup>

The physical stability of 10 parenteral nutrition admixtures with different amino acid sources was studied. The admixtures contained 500 mL each of dextrose 70%, fat emulsion 20% (Alpha Therapeutics), and amino acids in various concentrations from each manufacturer. Also present were standard electrolytes, trace elements, and vitamins. The admixtures were stored for 14 days at 4°C, followed by 4 days at 22 to 25°C. Slight creaming was evident in all admixtures but redispersed easily with agitation. Emulsion particles were uniform in size, showing no tendency to aggregate. No cracked emulsions occurred.<sup>1217</sup>

The stability of parenteral nutrition solutions containing amino acids, dextrose, and fat emulsion along with electrolytes, trace elements, and vitamins has been described. In one study the admixtures were stable for 24 hours at room temperature and for 8 days at 4°C. The visual appearance and particle size of the fat emulsion showed little change over the observation periods.<sup>1218</sup> In another study variable stability periods

were found, depending on electrolyte concentrations. Stability ranged from 4 to 25 days at room temperature.<sup>1219</sup>

The effects of dilution, dextrose concentration, amino acids, and electrolytes on the physical stability of 3-in-1 parenteral nutrition admixtures prepared with Intralipid 10% or Travamulsion 10% was studied. Travamulsion was affected by dilution up to 1:14, exhibiting an increase in mean particle size, while Intralipid remained virtually unchanged for 24 hours at 25°C and for 72 hours at 4°C. At dextrose concentrations above 15%, fat droplets larger than 5 µm formed during storage for 24 hours at either 4°C or room temperature. The presence of amino acids increased the stability of the fat emulsions in the presence of dextrose. Fat droplets larger than 5 µm formed at a total electrolyte concentration above approximately 240 mmol/L (monovalent cation equivalent) for Travamulsion 10% and 156 mmol/L for Intralipid 10% in 24 hours at room temperature, although creaming or breaking of the emulsion was not observed visually.<sup>1221</sup>

The stability of 43 parenteral nutrition admixtures composed of various ratios of amino acid products, dextrose 10 to 70%, and 4 lipid emulsions 10 and 20% with electrolytes, trace elements, and vitamins was studied. One group of admixtures included Travasol 5.5, 8.5, and 10%, FreAmine III 8.5 and 10%, Novamine 8.5 and 11.4%, Nephramine 5.4%, and RenAmine 6.5% with Liposyn II 10 and 20%. In another group, Aminosyn II 7, 8.5, and 10% was combined with Intralipid, Travamulsion, and Soyacal 10 and 20%. A third group consisted of Aminosyn II 7, 8.5, and 10% with electrolytes combined with the latter 3 lipid emulsions. The admixtures were stored for 24 hours at 25°C and for 9 days at 5°C followed by 24 hours at 25°C. A few admixtures containing FreAmine III and Novamine with Liposyn II developed faint yellow streaks after 10 days of storage. The streaks readily dispersed with gentle shaking, as did the creaming present in most admixtures. Other properties such as pH, zeta potential, and osmolality underwent little change in all of the admixtures. Particle size increased fourfold in one admixture (Novamine 8.5%, dextrose 50%, and Liposyn II in a 1:1:1 ratio), which the authors noted signaled the onset of particle coalescence. Nevertheless, the authors concluded that all of the admixtures were stable for the storage conditions and time periods tested.<sup>1222</sup>

The stability of 24 parenteral nutrition admixtures composed of various ratios of Aminosyn II 7, 8.5, or 10%, dextrose, and Liposyn II 10 and 20% with electrolytes, trace elements, and vitamins was studied. Four admixtures were stored for 24 hours at 25°C, 6 admixtures were stored for 2 days at 5°C followed by 1 day at 30°C, and 14 admixtures were stored for 9 days at 5°C followed by 1 day at 25°C. No visible instability was evident. Creaming was present in most admixtures but disappeared with gentle shaking. Other properties such as pH, zeta potential, particle size, and concentrations of the amino acids and dextrose showed little or no change during storage.<sup>1223</sup>

The emulsion stability of 5 parenteral nutrition formulas (TNA #126 through #130 in Appendix) containing Liposyn II in concentrations ranging from 1.2 to 7.1% were reported. The parenteral nutrition solutions were prepared using simultaneous pumping of the components into empty containers (as with the Nutrimix compounder) and sequential pumping of the

components (as with Automix compounders). The solutions were stored for 2 days at 5°C followed by 24 hours at 25°C. Similar results were obtained for both methods of preparation using visual assessment and oil globule size distribution.<sup>1426</sup>

The stability of 24 parenteral nutrition admixtures containing various concentrations of Aminosyn II, dextrose, and Liposyn II with a variety of electrolytes, trace elements, and multivitamins in dual-chamber, flexible, Nutrimix containers was studied as well. No instability was visible in the admixtures stored at 25°C for 24 hours or in those stored for 9 days at 5°C followed by 24 hours at 25°C. Creaming was observed, but neither particle coalescence nor free oil was noted. The pH, particle size distribution, and amino acid and dextrose concentrations remained acceptable during the observation period.<sup>1432</sup>

The physical stability of 10 parenteral nutrition formulas (TNA #149 through #158 in Appendix) containing TrophAmine and Intralipid 20%, Liposyn II 20%, and Nutrilipid 20% in varying concentrations with low and high electrolyte concentrations was studied. All test formulas were prepared with an automatic compounder and protected from light. TNA #149 through #156 were stored for 48 hours at 4°C followed by 24 hours at 21°C; TNA #157 and #158 were stored for 24 hours at 4°C followed by 24 hours at 21°C. Although some minor creaming occurred in all formulas, it was completely reversible with agitation. No other changes were visible, and particle size analysis indicated little variation during the study period. The addition of cysteine hydrochloride 1 g/25 g of amino acids, alone or with L-carnitine 16 mg/g fat, to TNA #157 and #158 did not adversely affect the physical stability of 3-in-1 admixtures within the study period.<sup>1620</sup>

The physical stability of five 3-in-1 parenteral nutrition admixtures (TNA #167 through #171 in Appendix) was evaluated by visual observation, pH and osmolality determinations, and particle size distribution analysis. All 5 admixtures were physically stable for 90 days at 4°C. However, some irreversible flocculation occurred in all combinations after 180 days.<sup>1651</sup>

The stability of several parenteral nutrition formulas (TNA #159 through #166 in Appendix) with and without iron dextran 2 mg/L was studied. All formulas were physically compatible both visually and microscopically for 48 hours at 4 and 25°C, and particle size distribution remained unchanged. The order of mixing and deliberate agitation had no effect on physical compatibility.<sup>1648</sup>

The maximum allowable concentrations of calcium and phosphate in a 3-in-1 parenteral nutrition mixture for children (TNA #192 in Appendix) were reported. Added calcium varied from 1.5 to 150 mmol/L, while added phosphate varied from 21 to 300 mmol/L. The mixtures were stable for 48 hours at 22 and 37°C as long as the pH was not greater than 5.7, the calcium concentration was below 16 mmol/L, the phosphate concentration was below 52 mM/L, and the product of the calcium and phosphate concentrations was below 250 mmol<sup>2</sup>/L<sup>2</sup> (mmol squared/liter squared).<sup>1773</sup>

The influence of 6 factors on the stability of fat emulsion in 45 different 3-in-1 parenteral nutrition mixtures was evaluated. The factors were amino acid concentration (2.5 to 7%); dextrose (5 to 20%); fat emulsion, intravenous (2 to 5%);

monovalent cations (0 to 150 mEq/L); divalent cations (4 to 20 mEq/L); and trivalent cations from iron dextran (0 to 10 mg elemental iron/L). Although many formulations were unstable, visual examination could identify instability in only 65% of the samples. Electronic evaluation of particle size identified the remaining unstable mixtures. Furthermore, only the concentration of trivalent ferric ions significantly and consistently affected the emulsion stability during the 30-hour test period. Of the parenteral nutrition mixtures containing iron dextran, 16% were unstable, exhibiting emulsion cracking. The authors suggested that iron dextran should not be incorporated into 3-in-1 mixtures.<sup>1814</sup>

The compatibility of 8 parenteral nutrition admixtures, 4 with and 4 without electrolytes, comparing Liposyn II and Intralipid (TNA #250 through #257 in Appendix) was reported. The 3-in-1 admixtures were evaluated over 2 to 9 days at 4°C and then 24 hours at 25°C in EVA bags. No substantial changes were noted in the fat particle sizes and no visual changes of emulsion breakage were observed. All admixtures tested had particle sizes in the 2- to 40- $\mu$ m range.<sup>2465</sup>

The stability of 3-in-1 parenteral nutrition admixtures prepared with Vamin 14 with electrolytes and containing either Lipofundin MCT/LCT 20% or Intralipid 20% was evaluated. The admixtures contained 66.7 mmol/L of monovalent and 6.7 mmol/L of divalent cations. Stability of the fat emulsion was evaluated after 2, 7, and 21 days at 4°C in EVA bags followed by 24 hours at room temperature to simulate infusion. Microscopy, Coulter counter, photon correlation spectroscopy, and laser diffractometry techniques were used to determine stability. Droplet size by microscopy was noted to increase to 18 to 20  $\mu$ m after 21 days in both of the admixtures with the Intralipid-containing admixture showing particles this large as early as day 2 and with Lipofundin MCT/LCT at day 7. The Coulter counter assessed particles greater than 2  $\mu$ m to be approximately 1300 to 1500 with Lipofundin MCT/LCT and 37,000 in the Intralipid-containing admixtures immediately after their preparation. Heavy creaming with a thick firm layer was noted after 2 days with the Intralipid-containing admixture, making particle assessment difficult. The authors concluded that storage limitation of 2 days for the Intralipid-containing admixture and not more than 7 days for the Lipofundin-containing admixture appeared justified. They also noted that calcium and magnesium behaved identically in destabilizing fat emulsion with greater concentrations of divalent cations.<sup>867</sup>

The physical instability of 3-in-1 TNA stored for 24 hours at room temperature was reported. The admixtures intended for use in neonates and infants were compounded with TrophAmine 2 to 3%, dextrose 18 to 24%, Liposyn II (Abbott) 2 to 3%, L-cysteine hydrochloride, and the following electrolytes:

Sodium	20 to 50 mEq/L
Potassium	13.3 to 40 mEq/L
Calcium chloride	20 to 26.6 mEq/L
Magnesium	3.4 to 5 mEq/L
Phosphates	6.7 to 15 mmol/L

The emulsion in the admixtures cracked and developed visible free oil within 24 hours after compounding. The incompatibility was considered to create a clinically significant risk of complications if the admixture was administered. The authors determined that these 3-in-1 TNA containing these concentrations of electrolytes were unacceptable and should not be used.<sup>2619</sup>

Another evaluation of 3-in-1 TNA reported physical instabilities of several formulations evaluated over 7 days. The parenteral nutrition admixtures were prepared with dextrose 15%, and Intralipos 4% (Fresenius Kabi) along with FreAmine 4.3%, NephAmine 2.1%, TrophAmine 2.7%, Topanusol 5%, or HepatAmine 4%. Various electrolytes and other components were also present including sodium, potassium, calcium (salt form unspecified), magnesium, trace elements, vitamin K, and heparin. The admixtures were stored at 4°C and evaluated at 0, 3, and 7 days. After removal from refrigeration, the samples were subjected to additional exposure to room temperature and temperatures exceeding 28°C for 24 to 48 hours. Flocculation was found in the admixtures prepared with FreAmine and with TrophAmine after 24 hours of storage at room temperature and after 3 days under refrigeration followed by 24 hours at room temperature. All of the admixtures developed coalescence after 7 days under refrigeration followed by 24 hours at greater than 28°C.<sup>2621</sup>

The physical stability of 5 highly concentrated 3-in-1 parenteral nutrition admixtures for fluid-restricted adults was evaluated. The admixtures were composed of Aminoplasmal (B. Braun) at concentrations over 7% as the amino acids source, dextrose concentrations of about 20%, and a 50:50 mixture of medium-chain triglycerides and long-chain triglycerides (Lipofundin MCT, B. Braun) at concentrations of about 2.5 to 2.7% as the lipid component with electrolytes and vitamins (TNA #269 through #273 in Appendix). The parenteral nutrition admixtures were prepared in EVA bags and stored at room temperature for 30 hours. Electronic evaluation of mean fat particle sizes and globule size distribution found little change over the 30-hour test period.<sup>2721</sup>

The physical stability of 64 formulations of 3-in-1 parenteral nutrition admixtures containing Smoflipid 20% (TNA #277 in Appendix) and 16 formulations of 3-in-1 parenteral nutrition admixtures containing Lipoplus 20% (TNA #278 in Appendix), both in combination with fixed amounts of dextrose 40% and amino acids (Neonutrin 15%) and variable amounts of electrolytes, was evaluated.<sup>3261</sup> Admixtures were stored in EVA bags for up to 29 days at 2 to 8°C followed by 24 hours at 23 to 25°C.<sup>3261</sup> Particle counts were assessed by optical microscopy.<sup>3261</sup> Although particle counts increased over time in admixtures containing either fat emulsion product, all admixtures remained stable throughout the study period and particle counts remained within limits.<sup>3261</sup> Formulations with Lipoplus 20% contained fewer large fat particles than those with Smoflipid 20%.<sup>3261</sup>

The drop size of 3-in-1 parenteral nutrition solutions in drip chambers is variable, being altered by the constituents of the mixture. In one study, multivitamins (Multibionta, E. Merck) caused the greatest reductions in drop size, up to 37%. This change may affect the rate of delivery if flow is estimated from drops per minute.<sup>1016</sup> Similarly, flow rates delivered by

infusion controllers dependent on predictable drop size may be inaccurate. Flow rates up to 29% less than expected have been reported. Therefore, variable-pressure volumetric pumps, which are independent of drop size, should be used rather than infusion controllers.<sup>1215</sup>

When using multicomponent, 3-in-1, parenteral nutrition admixtures, the following points should be considered:<sup>490 703 892 893 1025 1064 1070 1214 1324 1406 1670 2215 2282 2308 3251 3252 3253 3254 3255 3444</sup>

1. The order of mixing is important. The amino acid solution should be added to the dextrose prior to addition of the fat emulsion. This practice ensures that the protective effect of the amino acids to emulsion disruption by changes in pH and the presence of electrolytes is realized. Alternatively, some manufacturers of lipid emulsion state that all 3 components may be transferred to the admixture containers simultaneously, admixing with gentle agitation.
2. Electrolytes should not be added directly to the fat emulsion. Instead, they should be added to the amino acids or dextrose before the final mixing.
3. Such 3-in-1 admixtures containing electrolytes (especially divalent cations) are unstable and will eventually aggregate. The mixed systems should be carefully examined visually before use to ensure that a uniform emulsion still exists and that separation of the emulsion (i.e., "breaking" or "oiling out"), indicated by yellowish streaking or accumulation of yellowish droplets in the admixed emulsion, has not occurred.
4. Avoid contact of 3-in-1 parenteral nutrition admixtures with heparin, which destabilizes and damages the fat emulsion upon contact.
5. The admixtures should be stored under refrigeration if not used immediately.
6. The ultimate stability of the admixtures will be the result of a complex interaction of pH, component concentrations, electrolyte concentrations, and, probably, storage temperature.

Furthermore, a 1.2- $\mu\text{m}$  filter should be used in the administration of fat emulsion, intravenous, whether used alone or administered as a component of a TNA (3-in-1); filtration is necessary to remove large lipid particles, electrolyte precipitates, other solid particulates and aggregates.<sup>1106 1657 1769 2061 2135 2346 3251 3252 3253 3254 3255 3259 3260 3444</sup>

## Heparin

Heparin sodium has been stated to be compatible in fat emulsion.<sup>480 660</sup> The addition of heparin sodium (Abbott) 1 and 2 units/mL to Liposyn 10% and Intralipid 10% did not break the emulsion and effectively reversed the blood hypercoagulability associated with intravenous fat emulsion administration.<sup>568</sup>

Flocculation of fat emulsion (Kabi-Vitrum), however, has been reported during Y-site administration into a line used to infuse a parenteral nutrition solution containing both calcium gluconate and heparin sodium. Subsequent evaluation indicated that the combination of calcium gluconate (0.46 and 1.8 mmol/125 mL) and heparin sodium (25 and 100 units/125 mL) in amino acids plus dextrose induced flocculation of the fat emulsion within 2 to 4 minutes at concentrations that resulted in no visually apparent flocculation in 30 minutes with either agent alone.<sup>1214</sup>

Calcium chloride quantities of 1 to 20 mmol normally result in slow flocculation of fat emulsion 20% over several hours. When heparin sodium 5 units/mL was added, the flocculation rate was accelerated greatly and a cream layer was observed visually in a few minutes. This effect was not observed when sodium ion was substituted for the divalent calcium.<sup>1406</sup>

Similar results were observed during simulated Y-site administration of heparin sodium into nine 3-in-1 nutrient admixtures having different compositions. Damage to the fat emulsion component was found to occur immediately, with the possible formation of free oil over time.<sup>2215</sup>

The destabilization of fat emulsion (Intralipid 20%) when administered simultaneously with a TPN admixture and heparin was observed. The damage, detected by viscosity measurement, occurred immediately upon contact at the Y-site. The extent of the destabilization was dependent on the concentration of heparin and the presence of MVI Pediatric with its surfactant content. Additionally, phase separation was observed in 2 hours. The authors noted that TPN admixtures containing heparin should never be premixed with fat emulsion as a 3-in-1 TNA because of this emulsion destabilization. The authors indicated their belief that the damage could be minimized during Y-site co-administration as long as the heparin was kept at a sufficiently low concentration (no visible separation occurred at a heparin concentration of 0.5 unit/mL) and the length of tubing between the Y-site and the patient was minimized.<sup>2282</sup>

However, because the damage to emulsion integrity has been found to occur immediately upon mixing with heparin in the presence of the calcium ions in TPN admixtures<sup>1214 2215 2282</sup> and no evaluation and documentation of the clinical safety of using such destabilized emulsions has been performed, use of such damaged emulsions in patients is suspect.

## Amphotericin B

In an effort to reduce toxicity, amphotericin B has been admixed in Intralipid instead of the more usual dextrose 5%.<sup>1809 1810 1811 2178</sup> However, amphotericin B 0.75 mg/kg/day administered using this approach in 250 mL of Intralipid 20% has been associated with acute pulmonary toxicities, including sudden onset of coughing, tachypnea, agitation, cyanosis, and deterioration of oxygen saturation. The temporal relationship between the drug administration and respiratory symptoms suggested a causal relationship. Furthermore, no reduction in renal toxicity or other side effects associated with amphotericin B was observed. The authors concluded amphotericin B should not be administered to patients in Intralipid.<sup>2177</sup>

At a concentration of 0.6 mg/mL in Intralipid 10 or 20%, amphotericin B precipitated immediately or almost immediately. The precipitate was not visible to the unaided eye because of the emulsion's dense opacity. Particle size evaluation found thousands of particles larger than 10  $\mu\text{m}$  per mL. In dextrose 5%, very few particles were larger than 10  $\mu\text{m}$ . Centrifuging the Intralipid admixtures resulted in rapid visualization of the precipitate as a mass at the bottom of the test tubes.<sup>1808</sup>

Amphotericin B precipitation is observed in fat emulsion within 2 to 4 hours without centrifuging. In concentrations ranging from 90 mg/L to 2 g/L in Intralipid 20%, amphotericin

precipitate is easily seen as yellow particulate matter on the bottom of the lipid emulsion containers.<sup>1872 1988</sup> Damage to the emulsion integrity with creaming also has been reported.<sup>1987</sup>

In other reports, the appearance of problems was observed in as little as 15 minutes, and actual amphotericin B precipitate formed within 20 minutes of mixing. Analysis of the precipitate confirmed its identity as amphotericin B. The authors hypothesized that amphotericin B precipitates because the excipient deoxycholic acid, an anion, attracts oppositely charged choline groups from the egg yolk components of the fat emulsion and

forms a precipitate with phosphatidylcholine, leaving insufficient surfactant to keep the amphotericin B dispersed.<sup>2204 2205</sup>

### ***Plasma Expanders***

Fat emulsion (Abbott) 10 and 20% were combined with the plasma expanders Macrodex 6% in sodium chloride 0.9% (Schiwa), Gelafundin (Braun), Haes Steril 10% (Fresenius), and Expafusin Sine (Pfrimmer); fat particles exceeding 5  $\mu\text{m}$  resulted, as observed by microscopic examination. These combinations were incompatible.<sup>1668</sup>

## Fenoldopam Mesylate

AHFS 24:08.20

### Products

Fenoldopam mesylate is available as a concentrate for injection in 1- and 2-mL single-use ampuls.<sup>3241</sup> Each mL of the concentrate for injection contains fenoldopam 10 mg (as the mesylate salt), propylene glycol 518 mg, citric acid 3.44 mg, sodium citrate dihydrate 0.61 mg, and sodium metabisulfite 1 mg.<sup>3241</sup> The concentrate must be diluted for use.<sup>3241</sup>

To prepare a diluted solution of fenoldopam for continuous intravenous infusion in adult patients, 1, 2, or 4 mL of the concentrate for injection should be added to 250, 500, or 1000 mL, respectively, of sodium chloride 0.9% or dextrose 5% to yield a solution with a fenoldopam concentration of 40 mcg/mL.<sup>3241</sup>

To prepare a diluted solution for continuous intravenous infusion in pediatric patients, 0.6, 1.5, or 3 mL of the concentrate for injection should be added to 100, 250, or 500 mL, respectively, of sodium chloride 0.9% or dextrose 5% to yield a solution with a fenoldopam concentration of 60 mcg/mL.<sup>3241</sup>

### Trade Name(s)

Corlopam

### Administration

Fenoldopam mesylate is administered by continuous intravenous infusion only after dilution in dextrose 5% or sodium chloride 0.9%.<sup>3241</sup>

### Stability

Intact ampuls should be stored at 2 to 30°C.<sup>3241</sup> After dilution in dextrose 5% or sodium chloride 0.9%, fenoldopam mesylate is stable for 4 hours at room temperature or 24 hours when refrigerated prior to administration.<sup>3241</sup>

Solutions should be visually inspected for particulate matter and discoloration prior to administration; if particulate matter is present or cloudiness occurs, the solution should be discarded.<sup>3241</sup>

## Fentanyl Citrate

AHFS 28:08.08

### Products

Fentanyl citrate is available in 2-, 5-, 10-, and 20-mL ampuls, 2- and 5-mL syringe cartridges, and 30- and 50-mL vials. Each mL contains fentanyl (as the citrate) 50 mcg (0.05 mg) with hydrochloric acid and/or sodium hydroxide for pH adjustment.<sup>1(1/08) 4</sup>

### pH

From 4 to 7.5.<sup>1(1/08) 4</sup>

### Osmolality

The product osmolality was determined to be essentially 0 mOsm/kg.<sup>1233</sup>

### Trade Name(s)

Sublimaze

### Administration

Fentanyl citrate is administered by intramuscular or intravenous injection.<sup>1(1/08)</sup>

### Stability

Intact containers should be stored at controlled room temperature and protected from light. Brief exposure to temperatures up to 40°C does not affect concentration.<sup>1(1/08) 4</sup>

### pH Effects

Fentanyl citrate is most stable at pH 3.5 to 7.5.<sup>1638</sup> Fentanyl is hydrolyzed in acidic solutions.<sup>4</sup>

### Syringes

In 2015, reports of decreased potency of certain drugs (e.g., fentanyl citrate) stored in Becton Dickinson syringes for extended periods (i.e., exceeding 24 hours) were confirmed by the manufacturer of these syringes; the cause of this change was later identified to be the inclusion of an alternate rubber stopper in the plunger of certain product lots of syringes.<sup>3029 3036 3037 3039 3041 3042</sup> Decreased potency was not observed when the syringes were filled and used promptly.<sup>3037</sup> Use of the alternate stopper was later discontinued and use of the primary stopper in such syringes was resumed; however, Becton Dickinson states that its general-use syringes are cleared by FDA for immediate use in fluid aspiration and injection and that such syringes, regardless of the stopper material, have not been cleared by FDA for use as a closed-container system.<sup>3391</sup>

Undiluted fentanyl citrate 50 mcg/mL was tested for stability in polypropylene syringes. The fentanyl citrate injection was filled into polypropylene syringes that were then capped off. The samples were stored for 28 days under refrigeration at 5°C and at room temperature of 22°C exposed to light. No change in color or clarity occurred. No loss of fentanyl citrate at either set of storage conditions occurred.<sup>2648</sup>

Fentanyl citrate (Elkins Sinn) 0.0167 mg/mL in sodium chloride 0.9% packaged in polypropylene syringes (Sherwood) was physically stable and exhibited little or no loss in 24 hours stored at 4 or 23°C in the dark.<sup>2199</sup>

Fentanyl citrate (David Bull) 12.5 mcg/mL in sodium chloride 0.9% was packaged as 8 mL in 10-mL polypropylene syringes (Terumo) with attached needles. Fentanyl citrate (David Bull) 33.3 mcg/mL in sodium chloride 0.9% was packaged as 18 mL in 20-mL polypropylene syringes (Terumo) with attached needles. The syringes were stored at 5, 22, and 38°C for 7 days. The solutions were visually unchanged with no loss of drug at 5 and 22°C. At 38°C, the 12.5-mcg/mL solution had under 7% loss and the 33.3-mcg/mL solution had no loss.<sup>2202</sup>

Fentanyl citrate (Janssen) 35 mcg/mL in sodium chloride 0.9% was packaged in 2 types of polypropylene syringes. The Omnifix (B. Braun) syringes had polyisoprene piston tips while the Terumo syringes had no natural or synthetic rubber in the product. Stored at 4, 21, and 35°C for 30 days, the test solutions exhibited no visible or pH changes. Although the pH remained within the stability range for the drug, this does not demonstrate stability.<sup>2387</sup>

Fentanyl citrate (Hospira) was diluted to a concentration of 5 mcg/mL in sodium chloride 0.9% and packaged as 1.1 mL in 12-mL polypropylene syringes (Terumo).<sup>2791</sup> The syringes were stored for 90 days at a controlled temperature of 23 to 27°C and relative humidity of 55 to 65% while being protected from light.<sup>2791</sup> Neither changes in color or clarity nor appreciable changes in pH from baseline values occurred.<sup>2791</sup> Samples exhibited a loss of less than 1% at 90 days.<sup>2791</sup>

### Ambulatory Pumps

Fentanyl citrate (Merck) 50 and 30 mcg/mL in sodium chloride 0.9% was evaluated in CADD-1 and CADD-PRIZM medication cassettes. About 4% drug loss occurred in 14 days at room and refrigeration temperatures.<sup>2717</sup>

### Sorption

Fentanyl citrate 2 mcg/mL in various buffer solutions ranging from pH 5.5 to pH 6.7 packaged in polyvinyl chloride (PVC) containers (Baxter) was shown to undergo slow sorption to the PVC in amounts dependent on the pH of the solution. The lower pH solutions exhibited less loss with increasing loss as the pH increased. At the highest pH tested of 6.7, 17% fentanyl loss occurred in 1 day. Refrigeration decreased the extent of loss but did not eliminate it. See Table 1. Little or no fentanyl loss was found in identical fentanyl citrate 2-mcg/mL solutions packaged in glass containers.<sup>2305</sup>

Undiluted fentanyl citrate 50 mcg/mL was tested for stability in PVC bags. The fentanyl citrate injection was filled into PVC bags that were stored for 28 days under refrigeration at 5°C and

at room temperature of 22°C exposed to light. No change in color or clarity occurred. No loss of fentanyl citrate at either set of storage conditions occurred.<sup>2648</sup>

**Table 1. Percentage of fentanyl citrate 2 mcg/mL remaining after storage for 30 days at 23°C in PVC containers<sup>2305</sup>**

Buffer pH	Fentanyl Remaining (%)
5.5	85
5.8	77
6.3	56
6.7	27

### Filtration

Fentanyl citrate (Janssen) 2.5 mcg/mL in dextrose 5% or sodium chloride 0.9% was delivered over 4 hours through 3 kinds of 0.2-µm membrane filters varying in size and composition. No fentanyl loss occurred due to sorption to the filter.<sup>1399</sup>

### Central Venous Catheter

Fentanyl citrate (Abbott) 10 mcg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

### Solution Compatibility

## Ferric Carboxymaltose

AHFS 20:04.04

### Products

Ferric carboxymaltose injection is available as a dark brown colloidal solution in 15-mL single-use vials containing 750 mg of elemental iron.<sup>3374</sup> Each mL of the solution contains 50 mg of elemental iron in water for injection.<sup>3374</sup> Vials also may contain sodium hydroxide and/or hydrochloric acid to adjust the pH.<sup>3374</sup>

### pH

From 5 to 7.<sup>3374</sup>

### Tonicity

The undiluted solution of ferric carboxymaltose injection containing 50 mg of elemental iron per mL is isotonic.<sup>3374</sup>

### Trade Name(s)

Injectafer

### Administration

Ferric carboxymaltose injection is administered intravenously, either injected undiluted as a slow intravenous push or diluted in a compatible infusion solution for intravenous infusion.<sup>3374</sup>

For slow intravenous push administration, the drug should be administered undiluted at a rate of approximately 100 mg (2 mL)/min.<sup>3374</sup>

For intravenous infusion, doses of up to 750 mg of elemental iron should be diluted in up to 250 mL of sodium chloride 0.9% to yield a diluted solution for infusion with a concentration of elemental iron that is at least 2 mg/mL.<sup>3374</sup> Such diluted solutions for infusion should be administered over at least 15 minutes.<sup>3374</sup>

Extravasation of ferric carboxymaltose injection should be avoided as it may cause a persistent brown discoloration at the extravasation site.<sup>3374</sup> Patients should be monitored for extravasation of the drug during administration; if extravasation occurs, administration at that site should be discontinued.<sup>3374</sup>

### Compatibility Information

#### Solution Compatibility

##### Ferric carboxymaltose

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Sodium chloride 0.9%		AMR	2 to 4 g	Physically and chemically stable for 72 hr at room temperature	3374	C

© Copyright, March 2018. American Society of Health-System Pharmacists, Inc.

### Stability

Intact vials should be stored at controlled room temperature; freezing should be avoided.<sup>3374</sup>

In colloidal solutions such as ferric carboxymaltose colloidal solution, the complex may be destabilized if diluted too much;<sup>3375</sup> in order to maintain stability, ferric carboxymaltose injection should not be diluted to a concentration of elemental iron that is less than 2 mg/mL.<sup>3374</sup>

Ferric carboxymaltose injection should be visually inspected for particulate matter and discoloration prior to administration.<sup>3374</sup> Vials are for single use; any unused portion should be discarded.<sup>3374</sup>

Evaluating the stability of non-biological complex drugs, like ferric carboxymaltose, which are large, synthetic, and complex products, requires the use of a variety of assessments.<sup>3375</sup> In one study, ferric carboxymaltose (Vifor Pharma) injection was diluted in sodium chloride 0.9% to elemental iron concentrations of 1, 2, and 5 mg/mL in polypropylene bottles and bags.<sup>3375</sup> Stability tests showed that the total iron content in solutions (as assessed by complexometric titration with ethylenediaminetetraacetic acid [EDTA]) was within 10% of the theoretical iron content for up to 72 hours at room temperature (30°C) and 70 to 80% relative humidity.<sup>3375</sup> Additionally, the molecular weight distribution of ferric carboxymaltose was essentially unchanged.<sup>3375</sup> Diluted solutions of ferric carboxymaltose injection also were found to be free from sediment on visual inspection and had pH values and particle counts that were within the limits of acceptability during this study period.<sup>3375</sup>

### Sorption

In one study, ferric carboxymaltose (Vifor Pharma) injection diluted in sodium chloride 0.9% to elemental iron concentrations of 1, 2, and 5 mg/mL and stored for up to 72 h at 30°C and 70 to 80% relative humidity in polypropylene bottles and bags showed no measurable sorption of iron to the surface of the containers.<sup>3375</sup>

AHFS 20:04.04

### Products

Ferric derisomaltose injection is available as a dark brown, nontransparent solution in 1-, 5-, and 10-mL single-dose (preservative-free) vials containing 100, 500, and 1000 mg of elemental iron, respectively.<sup>3549</sup> Each mL of the solution contains 100 mg of elemental iron in water for injection.<sup>3549</sup>

### pH

Ferric derisomaltose injection has a pH ranging from 5 to 7.<sup>3549</sup>

### Trade Name(s)

Monoferric

### Administration

Ferric derisomaltose is administered as an intravenous infusion over at least 20 minutes after dilution of the drug in 100 to 500 mL

of sodium chloride 0.9% to a final concentration exceeding 1 mg of elemental iron per mL.<sup>3549</sup>

Extravasation of ferric derisomaltose injection should be avoided as it may cause a persistent brown discoloration at the extravasation site.<sup>3549</sup> Patients should be monitored for extravasation of the drug during administration; if extravasation occurs, administration at that site should be discontinued.<sup>3549</sup>

### Stability

Intact vials of ferric derisomaltose should be stored at controlled room temperature; freezing should be avoided.<sup>3549</sup>

Ferric derisomaltose injection should be visually inspected for particulate matter and discoloration prior to administration.<sup>3549</sup> The manufacturer states that the drug should not be mixed with or added to solutions containing other drugs.<sup>3549</sup>

## Ferumoxytol

AHFS 20:04.04

### Products

Ferumoxytol injection is available as a black to reddish brown colloidal solution in single-use (preservative-free) vials containing 510 mg of elemental iron.<sup>3550</sup> Each mL of the solution contains 30 mg of elemental iron, as well as polyglucose sorbitol carboxymethylether 30 mg and mannitol 44 mg.<sup>3550</sup>

### pH

Ferumoxytol injection has a pH ranging from 6 to 8.<sup>3550</sup>

### Tonicity

Ferumoxytol injection is isotonic.<sup>3550</sup>

### Osmolality

Ferumoxytol injection has an osmolality of 270 to 330 mOsmol/kg.<sup>3550</sup>

### Trade Name(s)

Feraheme

### Administration

Ferumoxytol is administered only as an intravenous infusion over at least 15 minutes after dilution of the drug in 50 to 200 mL of sodium chloride 0.9% or dextrose 5%.<sup>3550</sup>

### Stability

Intact vials of ferumoxytol should be stored at controlled room temperature.<sup>3550</sup>

Ferumoxytol injection should be visually inspected for particulate matter and discoloration prior to administration.<sup>3550</sup>

## Filgrastim

### AHFS 20:16

## Products

Filgrastim is available in 300- and 480-mcg vials and syringes with the product compositions and package configurations shown in Table 1.<sup>2873</sup>

**Table 1. Filgrastim products and compositions**<sup>2873</sup>

Water for injection qs	1 mL	1.6 mL	0.5 mL	0.8 mL

## Trade Name(s)

Neupogen

## Administration

Filgrastim is administered by subcutaneous injection undiluted or by intravenous or subcutaneous infusion.<sup>4 2873</sup> For intravenous infusion, it is diluted in 50 to 100 mL of dextrose 5% and given over 15 to 30 minutes, 60 minutes, or 4 hours or over 24 hours by continuous infusion.<sup>4 2873</sup> It may also be given over 24 hours by continuous subcutaneous infusion<sup>2873</sup> after diluting the dose in 10 to 50 mL of dextrose 5% and infusing at a rate not exceeding 10 mL/24 hours.<sup>4</sup> For extended infusions by either route, a controlled-infusion device is used.<sup>4</sup> For filgrastim concentrations of 5 to 15 mcg/mL, albumin human should be added to the infusion solution at a final concentration of 0.2% (2 mg/mL).<sup>2873</sup> The drug should not be diluted to concentrations less than 5 mcg/mL.<sup>2873</sup>

## Stability

Filgrastim injection is a clear, colorless solution.<sup>2873</sup> Intact containers should be refrigerated at 2 to 8°C and protected from direct sunlight.<sup>2873</sup> The product also should be protected from freezing<sup>2873</sup> and temperatures above 30°C to avoid aggregation.<sup>4</sup> The solution should not be shaken since this may damage the drug.<sup>2873</sup> If vigorous shaking and subsequent foaming has occurred, the solution should not be used.<sup>2873</sup>

Although refrigerated storage is required, the manufacturer has stated that filgrastim may be stored at room temperature for up to 24 hours,<sup>2873</sup> while others have stated that the drug is stable for 7 days at room temperature.<sup>2745</sup> The product is

packaged in single-use containers with no antibacterial preservative.<sup>2873</sup> The manufacturer recommends that vials not be reentered and that unused portions be discarded.<sup>2873</sup>

Filgrastim dilutions in dextrose 5% prepared for infusion should be stored under refrigeration and used within 24 hours of preparation because of concern about possible bacterial contamination.<sup>4</sup>

## pH Effects

Filgrastim is stable at pH 3.8 to 4.2, but stability is limited at neutral pH.<sup>4</sup>

## Syringes

Undiluted filgrastim is stable for 24 hours at 15 to 30°C and for 7 days refrigerated at 2 to 8°C repackaged in tuberculin syringes (Becton Dickinson). However, refrigeration and use within 24 hours are recommended because of concern about bacterial contamination.<sup>4</sup>

Although studies have found filgrastim in syringes remained sterile stored under refrigeration,<sup>1764 2186</sup> the sterility of repackaged injections is a function of the quality of the specific aseptic process of packaging, the quality of the environment in which the sterile product is packaged, and the capability of the personnel involved rather than a property of this unpreserved injection. Consequently, sterility is only valid for the specific facilities and operators for that specific test. The adequacy and safety of repackaging in another location or with other individuals or on another occasion should be verified independently for each institution and batch of repackaged filgrastim injection. Each institution needs to establish specific validation testing results for its own aseptic processing facilities, equipment, procedures, and personnel.<sup>1765 2187</sup> The potential for microbiological growth should be considered when assigning expiration periods.

The sterility of filgrastim 0.2 mL (60 mcg) extemporaneously drawn aseptically into tuberculin syringes and kept under "patient use" storage conditions was evaluated. The syringes were sent home with patients to be stored in their home refrigerators for 7 days and then were returned for sterility testing. A contamination rate as high as 1.25% was reported. The authors expressed the opinion and hope that the high rate of contamination was an artifact of the sterility testing itself. However, contamination during storage in the patients' refrigerators may have occurred.<sup>2294</sup>

## Sorption

Filgrastim in dextrose 5% at concentrations above 15 mcg/mL and between 2 and 15 mcg/mL with added albumin human 0.2% is compatible with common plastics used in syringes, administration sets, solution containers, and pump cassettes including polyvinyl chloride (PVC), polyolefin, and polypropylene.<sup>4</sup>

Filgrastim sorption occurs to a greater extent with lower concentrations and with longer infusion tubing.<sup>2601</sup> For filgrastim

concentrations between 5 and 15 mcg/mL, albumin human should be added to the infusion solution to make a final albumin human concentration of 0.2% (2 mg/mL) to minimize filgrastim adsorption to infusion containers and equipment.<sup>4</sup> At filgrastim concentrations above 15 mcg/mL, albumin human is unnecessary.<sup>4</sup> The product should not be diluted to a final concentration of less than 5 mcg/mL.<sup>2873</sup>

The amount of loss of filgrastim (Amgen) from the undiluted injection at a concentration of 300 mcg/mL when delivered through 6.6-French, single-lumen, silicone rubber, Broviac

catheters (Bard) was evaluated. The catheters were filled with dextrose 5% (about 0.45 mL) and flushed before and after introduction of the filgrastim. Injected amounts of filgrastim 300 mcg/mL ranged from 0.17 to 1 mL. The delivered flush solution was collected and analyzed for filgrastim content and activity. The lowest volume (0.17 mL) incurred about 32% loss of filgrastim upon delivery. The other volumes incurred lower losses, ranging from 12% to none. A second repeat filgrastim injection incurred similar losses. The filgrastim that was delivered through the catheters remained active.<sup>2017</sup>

## Floxacillin Sodium

AHFS 8:12.16.12

### Flucloxacillin Sodium

## Products

Floxacillin sodium is available in vials containing 250 mg, 500 mg, and 1 g of floxacillin as the sodium salt. To reconstitute for intramuscular use, add 1.5 mL of sterile water for injection to the 250-mg vial, 2 mL to the 500-mg vial, or 2.5 mL to the 1-g vial.<sup>38 115</sup>

For intravenous use, reconstitute the 250- or 500-mg vial with 5 to 10 mL and the 1-g vial with 15 to 20 mL of sterile water for injection. For intravenous infusion, the solution may be diluted further in a compatible infusion fluid.<sup>38 115</sup>

For intrapleural use, reconstitute the 250-mg vial with 5 to 10 mL of sterile water for injection. For intra-articular use, reconstitute the 250- or 500-mg vial with up to 5 mL of sterile water for injection or lidocaine hydrochloride 0.5% injection.<sup>38 115</sup>

For smaller doses, the reconstitution volumes in Table 1 will yield the indicated concentrations.

**Table 1. Floxacillin reconstitution volumes for smaller doses**<sup>38 115</sup>

Vial Size	Concentration (mg/1 mL)					
	50	100	125	200	250	500
250 mg	4.8 mL	2.3 mL	1.8 mL	1.05 mL		
500 mg		4.7 mL	3.7 mL	2.2 mL	1.7 mL	
1 g		9.3 mL			3.3 mL	1.3 mL

## Sodium and Magnesium Content

Each gram of drug contains 2.2 mmol (51 mg) of sodium and 1 mmol of magnesium.<sup>38 89 115</sup>

## Trade Name(s)

Floxapen, Ladropen

## Compatibility Information

### Solution Compatibility

#### Floxacillin sodium

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 2.5% in sodium chloride 0.45%		BE	1 g	6% loss in 24 hr at 20 to 25°C	89	C
Dextrose 5%				Under 10% loss in 24 hr at room temperature	1475	C
Dextrose 5%		BE	1 g	1% loss in 24 hr at 20 to 25°C	89	C

## Administration

Floxacillin sodium may be administered by intramuscular injection, direct intravenous injection slowly over three to four minutes, continuous intravenous infusion, and intrapleural and intra-articular injection.<sup>38</sup>

## Stability

Floxacillin sodium in intact vials should be stored below 25°C. The injection reconstituted for intramuscular or direct intravenous injection should be freshly prepared and administered within 30 minutes. However, reconstituted floxacillin sodium injection is stated to be stable for 24 hours when stored under refrigeration.<sup>38 115</sup>

Losses of 8% in three days were reported for reconstituted solutions containing floxacillin sodium (Beecham) 100 mg/mL stored at 20 to 25°C.<sup>89</sup>

## Freezing Solutions

Floxacillin sodium (Beecham) 20 mg/mL in sodium chloride 0.9% or dextrose 5% in PVC bags (Travenol) retained greater than 90% after being frozen and stored at -27°C for up to 270 days. Thawing by microwave radiation and subsequent storage for 24 hours at 4°C did not cause drug loss below 90% of the stated concentration. However, a distinct yellow discoloration was produced after 90 days of storage, rendering the solutions unacceptable.<sup>1176</sup>

Floxacillin sodium (Beecham) 1 g in 50 mL of sodium chloride 0.9% or dextrose 5% in PVC bags (Travenol) was stored at -20°C for 30 days, followed by natural thawing and storage at 5°C for 21 hours. The drug was stable under these conditions for the duration of the study.<sup>299</sup>

## Sorption

Floxacillin sodium was shown not to exhibit sorption to PVC bags and tubing, polyethylene tubing, Silastic tubing, and polypropylene syringes.<sup>536 606</sup>

## Floxuridine

### AHFS 10:00

#### Products

Floxuridine is supplied in 5-mL vials containing 500 mg of drug.<sup>3070</sup> Each vial should be reconstituted with 5 mL of sterile water for injection to yield a solution with a concentration of approximately 100 mg/mL.<sup>3070</sup>

#### pH

A 2% aqueous solution has a pH of 4 to 5.5.<sup>3070</sup>

#### Administration

Floxuridine is administered only by continuous regional intra-arterial infusion using an infusion pump after dilution in dextrose 5% or sodium chloride 0.9% to a volume appropriate for the device to be used.<sup>3070</sup>

#### Stability

Intact vials of floxuridine should be stored at 20 to 25°C.<sup>3070</sup> The reconstituted solution in vials should be stored under refrigeration at 2 to 8°C for no longer than 2 weeks.<sup>3070</sup>

The pH of optimum stability is 4 to 7. Extreme acidity or alkalinity may result in hydrolysis.<sup>1379</sup>

At a concentration of 5 mg/mL in sodium chloride 0.9%, floxuridine supported the growth of several microorganisms commonly implicated in nosocomial infections, including

*Escherichia coli*, *Pseudomonas aeruginosa*, and *Candida albicans*. The arbitrary application of an extended expiration date to floxuridine solutions is, therefore, highly questionable.<sup>827</sup>

#### Syringes

Floxuridine (Roche) 50 mg/mL and 1 mg/mL in sodium chloride 0.9% was packaged as 3 mL in 10-mL polypropylene infusion pump syringes (Pharmacia Deltec). Little or no loss occurred during 21 days of storage at 30°C.<sup>1967</sup>

#### Implantable Pumps

Floxuridine 10 mg/mL was filled into an implantable infusion pump (Fresenius VIP 30) and associated capillary tubing and stored at 37°C. No floxuridine loss and no contamination from components of pump materials occurred during 6 weeks of storage. However, an unidentified substance appeared in 7 weeks, and 22% loss of floxuridine occurred by 8 weeks.<sup>1903</sup>

Floxuridine (Roche) at concentrations ranging from about 2.5 to 12 mg/mL with heparin sodium 200 units/mL in bacteriostatic sodium chloride 0.9% was evaluated for stability in an implantable infusion pump (Infusaid model 400). In this in vivo assessment, the floxuridine concentrations were determined prior to implantation in patients and again at the time of pump refills. No appreciable floxuridine loss occurred during 8 courses of therapy, from 4 to 12 days in duration, in 5 patients.<sup>767</sup>

# Fluconazole

AHFS 8:14.08

## Products

Fluconazole is available for intravenous infusion in 100- and 200-mL glass bottles and polyvinyl chloride (PVC) bags in sodium chloride or dextrose diluents. Each mL of solution contains fluconazole 2 mg and either sodium chloride 9 mg or dextrose 56 mg.<sup>1(6/06)</sup>

## pH

From 4 to 8 in the sodium chloride diluent and from 3.5 to 6.5 in the dextrose diluent.<sup>1(6/06)</sup>

## Osmolarity

The infusion solution is iso-osmotic,<sup>1(6/06)</sup> having an osmolarity of 300 to 315 mOsm/L.<sup>4</sup>

## Trade Name(s)

Diflucan

## Administration

Fluconazole is administered by intravenous infusion at a rate not exceeding 200 mg/hr.<sup>1(6/06)</sup><sup>4</sup>

## Stability

Fluconazole injection in glass bottles or PVC bags should be stored between 5 and 30°C or between 5 and 25°C, respectively,

and protected from freezing. Brief exposure to temperatures up to 40°C does not adversely affect the product in PVC bags. The overwrap moisture barrier should not be removed from the PVC bags until ready for use. The solution should not be used if it is cloudy or precipitated.<sup>1(6/06)</sup><sup>4</sup>

## Elastomeric Reservoir Pumps

Fluconazole (Pfizer) 2 mg/mL in sodium chloride 0.9% was evaluated for binding to natural rubber elastomeric reservoirs (Baxter). Less than 2% binding was found after storage for 2 weeks at 35°C with gentle agitation.<sup>2014</sup>

## Central Venous Catheter

Fluconazole (Roerig) 2 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Final concentration after mixing.

<sup>d</sup> Tested in dextrose 5%, Ringer's injection, lactated, sodium chloride 0.45%, and sodium chloride 0.9%.

<sup>e</sup> Tested in dextrose 5% with albumin human 2 mg/mL.

<sup>f</sup> Lyophilized formulation tested.

<sup>g</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>h</sup> Varying volumes to simulate varying administration rates.

<sup>i</sup> Final concentrations were 1.5 mg/mL of fluconazole and 5 and 20 mcg/mL of tacrolimus.

<sup>j</sup> Tested in Ringer's injection, lactated.

<sup>k</sup> Tested in sterile water for injection.

<sup>l</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>m</sup> Ampicillin component. Ampicillin in a 2:1 fixed-ratio concentration with sulbactam.

<sup>n</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>o</sup> Quinupristin and dalfopristin components combined.

<sup>p</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>q</sup> Not specified whether concentration refers to single component or combined components.

<sup>r</sup> Test performed using the Cubicin formulation.

<sup>s</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>t</sup> Run at 25 mL/hr with dextrose 5% run at 83 mL/hr.

<sup>u</sup> Run at 100 mL/hr.

<sup>v</sup> Test performed using the formulation WITH edetate disodium.

<sup>w</sup> Tested as the premixed infusion solution.

## Fludarabine Phosphate

AHFS 10:00

### Products

Fludarabine phosphate is supplied as a lyophilized product in 6-mL vials containing 50 mg of drug with mannitol 50 mg and sodium hydroxide for pH adjustment. Reconstitute with 2 mL of sterile water for injection to yield a 25-mg/mL concentration.<sup>1(9/06)</sup>

Fludarabine phosphate is also available as a 50-mg/2 mL solution with disodium phosphate dihydrate and sodium hydroxide for pH adjustment.<sup>1(9/06)</sup>

### pH

From pH 7.2 to 8.2 for the reconstituted powder. From pH 7.3 to 7.7 for the liquid.<sup>1(9/06)</sup>

### Trade Name(s)

Fludara

### Administration

Fludarabine phosphate is administered by intravenous infusion over 30 minutes in 100 or 125 mL of dextrose 5% or sodium chloride 0.9%.<sup>1(9/06)</sup> 4 The drug also has been administered by rapid intravenous injection and continuous infusion, although the risk of toxicity may be increased.<sup>4</sup>

### Stability

Intact vials should be stored under refrigeration. The manufacturer recommends use of the reconstituted solution within

8 hours because it does not contain an antibacterial preservative.<sup>1(9/06)</sup> Nevertheless, the drug is chemically stable in solution, exhibiting less than 2% decomposition in 16 days when stored at room temperature and exposed to normal laboratory light.<sup>234</sup>

Fludarabine phosphate (Berlex) 0.2 mg/mL diluted in sodium chloride 0.9% and stored at 22°C did not exhibit an antimicrobial effect on the growth of *Enterococcus faecium*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Candida albicans* inoculated into the solution. Diluted solutions should be stored under refrigeration whenever possible, and the potential for microbiological growth should be considered when assigning expiration dates.<sup>2160</sup>

### pH Effects

Fludarabine phosphate is stable in aqueous solution at pH 4.5 to 8. The pH of optimum stability is approximately 7.6.<sup>234</sup>

### Sorption

Fludarabine phosphate 0.04 mg/mL in dextrose 5% or sodium chloride 0.9% was equally stable in either glass or polyvinyl chloride (PVC) containers, exhibiting no loss due to sorption during 48 hours at room temperature or under refrigeration.<sup>234</sup>

## Compatibility Information

### Solution Compatibility

#### Fludarabine phosphate

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 5%			1 g	Under 3% loss in 16 days at room temperature in light	234	C
Dextrose 5%			40 mg	No loss in 48 hr at room temperature or refrigerated	234	C
Sodium chloride 0.9%			1 g	Under 3% loss in 16 days at room temperature in light	234	C

# Flumazenil

AHFS 28:92

## Products

Flumazenil is available as a 0.1-mg/mL solution in 5- and 10-mL multiple-dose vials. In addition to flumazenil, each mL also contains methylparaben 1.8 mg, propylparaben 0.2 mg, sodium chloride 0.9%, edetate disodium 0.01%, and acetic acid 0.01%. The pH is adjusted with hydrochloric acid and, if necessary, sodium hydroxide.<sup>1(12/07)</sup>

## pH

The injection has a pH of approximately 4.<sup>1(12/07)</sup>

## Trade Name(s)

Romazicon

## Administration

Flumazenil is administered intravenously over 15 to 30 seconds. To minimize pain at the injection site, flumazenil should be administered through a freely running intravenous infusion line into a large vein. Extravasation should be avoided.<sup>1(12/07)</sup> 4

## Stability

Flumazenil injection is a stable aqueous solution; it should be stored at controlled room temperature. Discard the product 24 hours after removal from its original vial, whether admixed in an infusion solution or simply drawn into a syringe.<sup>1(12/07)</sup>

## Compatibility Information

## Fluorouracil

### AHFS 10:00

### 5-Fluorouracil

## Products

Fluorouracil injection is available in 10- and 20-mL single-use vials<sup>2955 2957</sup> and in 50- and 100-mL pharmacy bulk packages for preparation of individual doses.<sup>2954 2956</sup> Each mL contains fluorouracil 50 mg with sodium hydroxide for pH adjustment.<sup>2954 2955 2956 2957</sup>

## pH

The pH is adjusted to approximately 9.2<sup>2954 2955 2957</sup> with a range of 8.6 to 9.4.<sup>2956</sup>

## Administration

Fluorouracil is administered intravenously.<sup>2954 2955 2956 2957</sup> Care should be taken to avoid extravasation.<sup>2954 2955 2956 2957</sup> Dilution of the injection is not required for administration.<sup>2954 2955 2956 2957</sup> Fluorouracil also has been given by portal vein or hepatic artery infusion.<sup>4</sup>

In the event of spills or leaks, the use of sodium hypochlorite 5% (household bleach) to inactivate fluorouracil is recommended.<sup>1200</sup>

## Stability

Fluorouracil is normally colorless to faint yellow<sup>2956</sup> or yellow.<sup>2954 2955</sup> Its stability and safety are not affected by slight discoloration that may occur during storage.<sup>2954 2955 2956 2957</sup> It should be stored at controlled room temperature and protected from light.<sup>2954 2955 2956 2957</sup> and freezing.<sup>2954 2955</sup> Some manufacturers recommend storing the vials in the original cartons until the time of use.<sup>2956 2957</sup> The color of the solution results from the presence of free fluorine. A dark yellow indicates greater decomposition. Such decomposition may result from storage for several months at temperatures above room temperature. It is suggested that solutions having a darker yellow color be discarded.<sup>398</sup> Exposure to sunlight or intense incandescent light also has caused degradation. The solutions changed to dark amber to brown.<sup>760</sup> A precipitate may form from exposure to low temperatures and may be resolubilized by heating to 60°C with vigorous shaking.<sup>2954 2955 2956 2957</sup> The solution should then be allowed to cool to body temperature before administration.<sup>2954 2955 2956 2957</sup>

Microwave radiation also has been used to resolubilize the precipitate. Ampuls of fluorouracil (no longer commercially available in the US) containing a precipitate were exposed to microwave radiation and shaken until clear. These ampuls were then compared to ampuls that were heated to 60°C and shaken until clear and also to unheated controls. The precipitate was redissolved by microwave radiation without significantly affecting the drug. No significant decrease in concentration was observed. There was a slight change in pH. The authors concluded that microwave radiation was a suitable

method for solubilizing the precipitate that may form in fluorouracil ampuls. However, they warned that extreme care should be taken to avoid overheating and the resulting explosions from excessive pressure in the ampuls.<sup>662</sup>

Fluorouracil (Roche) 1 mg/mL in dextrose 5% was evaluated for stability in translucent containers (Perfupack Y, Baxter) and 5 opaque containers (green polyvinyl chloride [PVC] Opafuseur [Bruneau], white ethylene vinyl acetate [EVA] Perfu-opaque [Baxter], orange PVC PF170 [Cair], white PVC V86 [Codan], and white EVA Perfecran [Fandre]) when exposed to sunlight for 28 days. No photodegradation or sorption was found. However, an increase in concentration due to moisture permeation was detected after 2 weeks.<sup>1750</sup>

Immersion of a needle with an aluminum component in fluorouracil (Adria) 50 mg/mL resulted in no visually apparent reaction after 7 days at 24°C.<sup>988</sup>

Fluorouracil (Adria) 500 mg/10 mL did not support the growth of several microorganisms commonly implicated in nosocomial infections. The bacteriostatic properties were observed against *Escherichia coli*, *Klebsiella pneumoniae*, *Staphylococcus epidermidis*, *Pseudomonas aeruginosa*, *Candida albicans*, and *Clostridium perfringens*.<sup>828</sup>

In another study, fluorouracil (Adria) 1 g/20 mL transferred to PVC containers did not support the growth of several microorganisms and may have imparted an antimicrobial effect at this concentration. Loss of viability was observed for *Staphylococcus aureus*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Pseudomonas cepacia*, *Candida albicans*, and *Aspergillus niger*.<sup>1187</sup>

Fluorouracil eliminated the viability of *Staphylococcus epidermidis* (10<sup>6</sup> to 10<sup>7</sup> CFU/mL) in varying time periods, depending on concentration and diluent, when stored at near-body temperature (35°C). At 50 mg/mL, no viability was found after 5 days of incubation. At 10 mg/mL in sodium chloride 0.9% and dextrose 5%, no viability was found after 7 and 5 days, respectively. Following dilution to 10 mg/mL with bacteriostatic sodium chloride 0.9%, no viability was found after 2 days.<sup>1659</sup>

## pH Effects

At a pH greater than 11, slow hydrolysis of fluorouracil occurs. At a pH less than 8, solubility is reduced and precipitation may or may not occur, depending on the concentration.<sup>1369 1379</sup>

Fluorouracil 50 mg/mL (Lyphomed, Roche, and SoloPak) exhibited precipitation in 2 to 4 hours at pH 8.6 to 8.68; precipitation occurred immediately at pH 8.52 or less. The precipitate consisted of needle-shaped crystals at pH 8.26 to 8.68. Cluster-shaped crystals formed at pH 8.18 and below.<sup>1489</sup>

Admixture with acidic drugs or drugs that decompose in an alkaline environment should be avoided.<sup>524</sup>

A color change to deep purple was reported for the mixtures of doxorubicin hydrochloride (Adria) 10 mg/L with fluorouracil (Roche) 250 mg/L in dextrose 5%.<sup>296</sup> This color change is indicative of decomposition occurring in solutions with an alkaline pH. It also occurs with other anthracyclines.<sup>394</sup>

### Freezing Solutions

Fluorouracil (Abic) 5 mg/0.5 mL in sodium chloride 0.9% in polypropylene syringes (Plastipak, Becton Dickinson) was stored frozen at  $-20^{\circ}\text{C}$ . No fluorouracil loss occurred in 8 weeks. Refreezing and further storage at  $-20^{\circ}\text{C}$  for another 2 weeks also did not result in a fluorouracil loss.<sup>1666</sup>

Fluorouracil (Teva) near 6.8 mg/mL in sodium chloride 0.9% in PVC bags was stored frozen at  $-20^{\circ}\text{C}$  for 79 days, thawed in a microwave oven, and stored for an additional 28 days under refrigeration. No precipitation or crystallization occurred. No fluorouracil loss occurred after frozen storage and about 6% loss occurred after the subsequent refrigerated storage.<sup>2807</sup>

### Syringes

Fluorouracil 25 mg/mL in polypropylene syringes (Braun Omnifix) was stable for 28 days at 4 and  $20^{\circ}\text{C}$ .<sup>1564</sup>

Fluorouracil (Roche) 50 mg/mL was packaged as 3 mL in 10-mL polypropylene infusion pump syringes (Pharmacia Deltec). Little or no loss occurred during 21 days of storage at  $30^{\circ}\text{C}$ .<sup>1967</sup>

Fluorouracil (Roche) 12 and 40 mg/mL diluted with sodium chloride 0.9% and dextrose 5% was packaged in 60-mL polypropylene syringes and stored at  $25^{\circ}\text{C}$  protected from light. Losses of 5% or less occurred in the solutions after storage for 72 hours. Furthermore, the solutions had no visually apparent precipitate or discoloration.<sup>1983</sup>

### Ambulatory Pumps

The stability of undiluted fluorouracil 50 mg/mL from 3 manufacturers (Lyphomed, Roche, and SoloPak) in the reservoirs of 4 portable infusion pumps (Pharmacia Deltec CADD-1, Model 5100; Cormed II, Model 10500; Medfusion Infumed 200; and Pancretec Provider I.V., Model 2000) was evaluated. The fluorouracil was delivered by the pumps at a rate of 10 mL/day over a 7-day cycle at 25 and  $37^{\circ}\text{C}$ . All fluorouracil samples in all pump reservoirs were stable over the 7-day study period, exhibiting little or no drug loss and only minimal leached plasticizer, diethylhexyl phthalate (DEHP), at either temperature.<sup>1489</sup>

However, precipitation of the Roche fluorouracil was observed with all pumps; a fine white precipitate originated close to the connection junction and migrated in both directions until it occupied most of the tubing and was in the drug reservoir. In some cases, the pumps stopped due to the extent of precipitation. The authors noted that various factors, including solution pH, temperature, drug concentration and solubility, and the manipulative techniques used could contribute to precipitate formation.<sup>1489</sup>

Undiluted fluorouracil (Roche) 50 mg/mL in EVA bags for use with portable infusion pumps remained stable, with little or no loss after 28 days at 4, 22, and  $35^{\circ}\text{C}$ . The containers at  $35^{\circ}\text{C}$  did sustain approximately a 3% water loss due to evaporation during storage, increasing the fluorouracil concentration slightly.<sup>1548</sup>

Fluorouracil (David Bull Laboratories) 25 mg/mL was stable in PVC reservoirs (Parker Micropump) for 14 days at 4 and  $37^{\circ}\text{C}$ , exhibiting no loss.<sup>1696</sup>

The stability of undiluted fluorouracil injection (Roche) 50 mg/mL in EVA reservoirs (Celsa) and PVC reservoirs (Pharmacia) for use with ambulatory infusion pumps was evaluated. The filled reservoirs were stored for 14 days at  $4^{\circ}\text{C}$  and at  $33^{\circ}\text{C}$  to simulate the conditions of prolonged infusion from the reservoirs kept under patients' clothing. No loss of fluorouracil due to decomposition was found. However, the refrigerated samples exhibited substantial (up to 15%) loss of drug content from solution due to gross precipitation. Flocculent precipitation was observed in as little as 3 days, though subvisible precipitation may occur earlier. At the elevated temperature, substantial increases in concentration of fluorouracil occurred in the EVA reservoirs due to water loss from permeation through the plastic reservoir. Approximately 5% increase in drug concentration occurred in 14 days. No change in concentration occurred in the PVC reservoirs during this time frame.<sup>2004</sup>

### Implantable Pumps

Fluorouracil 50 mg/mL was filled into an implantable infusion pump (Fresenius VIP 30) and associated capillary tubing and stored at  $37^{\circ}\text{C}$ . No fluorouracil loss and no contamination from components of pump materials occurred during 8 weeks of storage.<sup>1903</sup>

Fluorouracil combined with leucovorin calcium for repeated administration using a Fresenius implanted port resulted in blockage of the pump catheter and necessitated surgical removal of the port. The blockage was caused by precipitation of calcium carbonate in the catheter.<sup>2504</sup>

### Sorption

Fluorouracil was shown not to exhibit sorption to PVC bags and tubing, polyethylene bags or tubing, Silastic tubing, and polypropylene and polyethylene syringes.<sup>536 606 760 2420 2430</sup>

Fluorouracil may be more extensively adsorbed to glass surfaces than to plastic. In one report, significant loss occurred from solutions in glass vials, but almost quantitative recovery was obtained from polyethylene and polypropylene plastic vials. The loss was attributed to adsorption to the glass surface.<sup>663</sup> This difference was also observed in dextrose 5% in glass and PVC infusion containers. A 10% loss of fluorouracil occurred in 43 hours in the PVC containers but in only 7 hours in the glass containers.<sup>519</sup>

### Filtration

Fluorouracil 10 to 75 mcg/mL exhibited little or no loss due to sorption to either cellulose nitrate/cellulose acetate ester (Millex OR) or Teflon (Millex FG) filters.<sup>1415 1416</sup>

### Central Venous Catheter

Fluorouracil (Roche) 5 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

### Solution Compatibility

#### Fluorouracil

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I

## Fluphenazine Hydrochloride

AHFS 28:16.08.24

### Products

Fluphenazine hydrochloride is available in 10-mL multiple-dose vials. Each mL contains fluphenazine hydrochloride 2.5 mg with sodium chloride for isotonicity, sodium hydroxide or hydrochloric acid to adjust the pH, and methylparaben 0.1% and propylparaben 0.01% as preservatives.<sup>1(9/08)</sup> 4

### pH

From 4.8 to 5.2.<sup>1(9/08)</sup> 4

### Administration

Fluphenazine hydrochloride is administered by intramuscular injection.<sup>1(9/08)</sup> 4

### Stability

Intact vials should be stored at controlled room temperature and protected from freezing and light. Parenteral solutions of fluphenazine hydrochloride vary from colorless to light amber. Solutions that are darker than light amber, are discolored in some other way, or contain a precipitate should not be used.<sup>1(9/08)</sup> 4

## Folic Acid

AHFS 88:08

### Products

Folic acid 5 mg/mL injection is available in 10-mL vials. Each mL of solution also contains edetate sodium 5 mg, benzyl alcohol 2 mg, and hydrochloric acid and/or sodium hydroxide to adjust pH in water for injection.<sup>1(1/08)</sup>

### pH

From 8 to 11.<sup>1(1/08)</sup> 4

### Administration

Folic acid injection is administered by deep intramuscular, intravenous, or subcutaneous injection.<sup>1(1/08)</sup> 4

### Stability

Intact vials should be stored at controlled room temperature and protected from light.<sup>1(1/08)</sup> The yellow to orange-yellow solutions are heat sensitive and should be protected from light<sup>4</sup> for long-term storage. However, exposure of folic acid in parenteral nutrition solutions to fluorescent light for 48 hours did not cause any significant loss of folic acid.<sup>896</sup>

### pH Effects

Folic acid is soluble in solutions of pH 5.6 or above at room temperature to a concentration of 1 g/L. However, below about pH 4.5 to 5, folic acid may precipitate in varying time periods, depending on the acidity of the solution. In the small concentrations used for parenteral nutrition, a pH of above 5 ensures that folic acid will remain in solution. Most parenteral nutrition solutions are buffered by the amino acids to pH 5 to 6.<sup>895</sup>

The rate of folic acid photodegradation is higher in an acidic medium compared to the rate in an alkaline medium.<sup>2496</sup>

### Sorption

A parenteral nutrition solution containing 13 mcg/L of folic acid injection in a 3-L polyvinyl chloride (PVC) bag and run through an administration set delivered the full amount of folic acid, with no loss.<sup>895</sup>

### Filtration

Folic acid (Lederle) 0.5 mg/L in dextrose 5% and sodium chloride 0.9% was filtered at 120 mL/hr for 6 hours through a 0.22- $\mu$ m cellulose ester membrane filter (Ivex-2). No significant reduction due to binding to the filter was noted.<sup>533</sup>

## Additional Compatibility Information

### Parenteral Nutrition Solutions

A 40% drop in folic acid concentration occurred immediately after admixture in a parenteral nutrition solution composed of amino acids, dextrose, electrolytes, trace elements, and multivitamins in PVC bags. The folic acid concentration then remained relatively constant for 28 days when stored at both 4 and 25°C.<sup>1063</sup>

Extensive decomposition of ascorbic acid and folic acid was reported in a parenteral nutrition solution composed of amino acids 3.3%, dextrose 12.5%, electrolytes, trace elements, and M.V.I.-12 (USV) in PVC bags. Half-lives were 1.1, 2.9, and 8.9 hours for ascorbic acid and 2.7, 5.4, and 24 hours for folic acid stored at 24°C in daylight, 24°C protected from light, and 4°C protected from light, respectively. The decomposition was much greater than for solutions not containing catalyzing metal ions. Also, it was greater than for the vitamins singly because of interactions with the other vitamins present.<sup>1059</sup>

Because of these interactions, recommendations to separate the administration of vitamins and trace elements have been made.<sup>1056 1060 1061</sup> Other researchers have termed such recommendations premature based on differing reports<sup>895 896</sup> and the

apparent absence of epidemic vitamin deficiency in parenteral nutrition patients.<sup>1062</sup>

The stability of several vitamins from M.V.I.-12 (Armour) admixed in parenteral nutrition solutions composed of different amino acid products, with or without Intralipid 10%, in glass bottles and PVC bags at 25 and 5°C for 48 hours was reported. Folic acid was stable in all samples.<sup>1431</sup>

In another study, the stability of several vitamins (from M.V.I.-12) following admixture with 4 different amino acid products (FreAmine III, Neopham, Novamine, Travasol) with or without Intralipid when stored in glass bottles or PVC bags at 25°C for 48 hours was reported. High-intensity phototherapy light did not affect folic acid. When bisulfite was added to the Neopham admixture, folic acid was unaffected. The authors concluded that intravenous multivitamins should be added to parenteral nutrition admixtures immediately prior to administration to reduce losses of vitamins other than folic acid since commercially available amino acid products may contain bisulfites and have varying pH values.<sup>487</sup>

The vitamins in Cernevit (Baxter) diluted in three 2-in-1 parenteral nutrition admixtures were tested for stability over 48 hours. Most of the other vitamins, including folic acid, retained their initial concentrations.<sup>2796</sup>

## Fomepizole

AHFS 92:12

### Products

Fomepizole concentrate for injection is available in single-use (unpreserved) vials containing 1.5 g of fomepizole.<sup>3130 3131</sup> The concentrate must be diluted prior to administration.<sup>3130 3131</sup> The appropriate dose of the concentrate should be withdrawn from the vial with a syringe and diluted in at least 100 mL of sodium chloride 0.9% or dextrose 5%; the solution should be mixed well.<sup>3130 3131</sup>

### Trade Name(s)

Antizol

### Administration

Fomepizole concentrate for injection is administered intravenously as a slow infusion over 30 minutes following dilution of the drug in at least 100 mL of sodium chloride 0.9% or dextrose 5%.<sup>3130 3131</sup> Fomepizole should *not* be administered undiluted or by bolus injection.<sup>3130 3131</sup>

## Compatibility Information

### Solution Compatibility

#### Fomepizole

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 5%		PAL		Stated to be stable for 24 hr if stored under refrigeration or at room temperature	3131	C
Sodium chloride 0.9%		PAL		Stated to be stable for 24 hr if stored under refrigeration or at room temperature	3131	C

© Copyright, May 2016. American Society of Health-System Pharmacists, Inc.

### Stability

Fomepizole concentrate for injection is a clear to yellow solution at room temperature.<sup>3130 3131</sup> Intact vials should be stored at controlled room temperature.<sup>3130 3131</sup>

Solutions diluted for infusion in sodium chloride 0.9% or dextrose 5% are stated to be stable for 24 hours when stored under refrigeration or at room temperature; solutions should not be used beyond 24 hours.<sup>3130 3131</sup>

Solutions diluted for infusion should be visually inspected for particulate matter prior to administration.<sup>3130 3131</sup> If haziness, particulate matter, discoloration, or precipitation is present or if leakage occurs, the solution should not be used.<sup>3130 3131</sup>

Fomepizole concentrate solidifies at temperatures less than 25°C.<sup>3130 3131</sup> If the fomepizole concentrate becomes solid in the vial, the vial should be passed under warm water or held in the hand to liquify the drug.<sup>3130 3131</sup> Solidification does not affect the efficacy, safety, or stability of fomepizole.<sup>3130 3131</sup>

## Fosaprepitant Dimeglumine

AHFS 56:22.32

### Products

Fosaprepitant is available as a lyophilized powder in single-use vials containing fosaprepitant dimeglumine equivalent to 150 mg of fosaprepitant as the free acid.<sup>2998</sup> Also present in each vial are edetate disodium 18.8 mg, polysorbate 80 75 mg, lactose anhydrous 375 mg, and sodium hydroxide and/or hydrochloric acid to adjust the pH.<sup>2998</sup>

Each 150-mg vial should be reconstituted with 5 mL of sodium chloride 0.9%, directing the stream of diluent along the vial wall to prevent foaming.<sup>2998</sup> The vial should be gently swirled to dissolve the powder; shaking should be avoided.<sup>2998</sup> After reconstitution, the solution should be further diluted to a concentration of 1 mg/mL by transferring the entire vial contents to an infusion bag containing 145 mL of sodium chloride 0.9% and gently inverting the bag 2 to 3 times.<sup>2998</sup> The diluted solution should be inspected for particulate matter and discoloration prior to infusion.<sup>2998</sup>

### Trade Name(s)

Emend

### Administration

Fosaprepitant dimeglumine is administered by intravenous infusion over 15 minutes or 20 to 30 minutes (depending on the indicated use) after dilution in sodium chloride 0.9% to a concentration of 1 mg/mL.<sup>2998</sup>

### Stability

Intact vials should be stored under refrigeration at 2 to 8°C.<sup>2998</sup> The manufacturer states that the diluted solution is stable for 24 hours at or below 25°C.<sup>2998</sup>

Fosaprepitant is incompatible with any solutions containing divalent cations (e.g., calcium, magnesium), including Ringer's injection, lactated and Hartmann's solution.<sup>2998</sup>

## Foscarnet Sodium

AHFS 8:18.92

### Products

Foscarnet sodium is available as a 24-mg/mL solution of the drug (as the hexahydrate) in water for injection in 250-mL (6 g of foscarnet sodium hexahydrate) glass bottles.<sup>3022</sup> Hydrochloric acid may have been added to adjust the pH.<sup>3022</sup>

### pH

Adjusted to pH 7.4.<sup>3022</sup>

### Sodium Content

Foscarnet sodium contains 5.5 mg of sodium per mL of solution.<sup>3022</sup>

### Tonicity

Foscarnet sodium injection is isotonic.<sup>3022</sup>

### Trade Name(s)

Foscavir

### Administration

Foscarnet sodium is administered by intravenous infusion.<sup>3022</sup> An infusion pump *must* be used for administration to prevent rapid infusion; the drug should *not* be administered by rapid or bolus intravenous injection.<sup>3022</sup>

Foscarnet sodium should only be infused into veins with adequate blood flow to allow for rapid dilution and distribution.<sup>3022</sup> For peripheral administration, foscarnet sodium solution must be diluted to a concentration of 12 mg/mL with dextrose 5% or sodium chloride 0.9% to avoid local irritation of peripheral veins.<sup>3022</sup> For administration through a central venous catheter, the 24-mg/mL solution may be infused undiluted.<sup>3022</sup>

Adequate hydration to establish diuresis is recommended in patients receiving foscarnet sodium provided there are no clinical contraindications.<sup>3022</sup> It is recommended that patients receive hydration with 750 to 1000 mL of sodium chloride 0.9% or dextrose 5% prior to the first infusion of foscarnet sodium.<sup>3022</sup> With subsequent infusions, hydration should be administered concurrently with each infusion of foscarnet sodium.<sup>3022</sup> For foscarnet sodium doses of 90 to 120 mg/kg, 750 to 1000 mL of hydration fluid should be administered; for doses of 40 to 60 mg/kg, 500 mL of hydration fluid should be administered, although hydration may be decreased if clinically warranted.<sup>3022</sup>

Foscarnet sodium should be infused over at least 1 to 2 hours, depending upon the indication, dosage, and regimen

(e.g., induction, maintenance).<sup>3022</sup> The rate of infusion must not exceed 1 mg/kg/min.<sup>3022</sup> Recommended dosage, frequency, and administration rates should not be exceeded.<sup>3022</sup>

### Stability

Foscarnet sodium injection is a clear, colorless solution.<sup>3022</sup> Intact bottles should be stored at controlled room temperature and protected from temperatures above 40°C and from freezing.<sup>3022</sup> Refrigerated products or products exposed to temperatures below freezing may exhibit precipitation; however, the precipitate can be dissolved by bringing the bottle to room temperature and with repeated shaking.<sup>3022</sup> The product should be used only if the bottle and seal are intact and a vacuum is present.<sup>3022</sup>

The manufacturer states that foscarnet sodium solutions diluted for infusion should be used within 24 hours of initial entry into a sealed bottle.<sup>3022</sup>

Foscarnet sodium may chelate divalent metal ions (e.g., calcium, magnesium) and is chemically incompatible with solutions containing calcium, such as Ringer's injection, lactated, and parenteral nutrition solutions.<sup>3022</sup>

Foscarnet sodium (Astra) diluted to a concentration of 13 mg/mL in sodium chloride 0.9% and stored at 22°C did not exhibit an antibacterial effect on the growth of 3 organisms (*Enterococcus faecium*, *Staphylococcus aureus*, and *Pseudomonas aeruginosa*) that were inoculated into the solution. Foscarnet sodium exhibited moderate antifungal activity against *Candida albicans*. The authors recommended that ready-to-use solutions be stored under refrigeration whenever possible and that the potential for microbiological growth be considered when assigning expiration periods.<sup>2160</sup>

### Autoclaving

The concentration of foscarnet sodium (Astra), diluted in sodium chloride 0.9% to a concentration of 12 mg/mL and packaged in glass infusion bottles with rubber bungs, was compared before and after autoclaving at 30 psi for 15 minutes at 121°C. The foscarnet sodium concentration did not change after autoclaving. Therefore, the dilution may be autoclaved to avoid limiting its shelf life due to sterility concerns.<sup>1835</sup>

### Elastomeric Reservoir Pumps

Foscarnet sodium (Astra) 24 mg/mL was evaluated for binding potential to natural rubber elastomeric reservoirs (Baxter). No binding was found after storage for 2 weeks at 35°C with gentle agitation.<sup>2014</sup>

# Fosnetupitant Chloride Hydrochloride–Palonosetron Hydrochloride

## AHFS 56:22.32

### Products

Fosnetupitant is a prodrug that is converted in vivo to netupitant via metabolic hydrolysis.<sup>3428</sup> Fosnetupitant–palonosetron is available as a lyophilized powder in single-dose (preservative-free) vials containing fosnetupitant chloride hydrochloride equivalent to 235 mg of fosnetupitant and palonosetron hydrochloride equivalent to 0.25 mg of palonosetron.<sup>3428</sup> Also present in each vial are edetate disodium 6.4 mg, mannitol 760 mg, and sodium hydroxide and/or hydrochloric acid to adjust the pH.<sup>3428</sup>

Each vial of fosnetupitant chloride hydrochloride–palonosetron hydrochloride should be reconstituted with 20 mL of dextrose 5% or sodium chloride 0.9%, directing the stream of diluent along the vial wall and swirling the vial gently to prevent foaming.<sup>3428</sup> The entire volume of the reconstituted solution should then be withdrawn from the vial and transferred to an infusion vial or bag containing 30 mL of dextrose 5% or sodium chloride 0.9% to yield a final total volume of 50 mL.<sup>3428</sup> The vial or bag should be gently inverted until dissolution is complete.<sup>3428</sup>

### Equivalency

Fosnetupitant chloride hydrochloride 260 mg is equivalent to fosnetupitant 235 mg.<sup>3428</sup>

Palonosetron hydrochloride 0.28 mg is equivalent to palonosetron 0.25 mg.<sup>3428</sup>

### Trade Name(s)

Akynzeo

### Administration

Fosnetupitant chloride hydrochloride–palonosetron hydrochloride should be administered as an intravenous infusion over

30 minutes after reconstitution and dilution.<sup>3428</sup> The infusion line should be flushed at the end of the infusion with the same solution used for reconstitution and dilution of the drug.<sup>3428</sup> In addition, if a common infusion line is being used to administer other drugs, the line should be flushed with sodium chloride 0.9% prior to and following infusion of fosnetupitant chloride hydrochloride–palonosetron hydrochloride.<sup>3428</sup>

### Stability

Fosnetupitant chloride hydrochloride–palonosetron hydrochloride is a white to off-white lyophilized powder.<sup>3428</sup> Intact vials should be stored at 2 to 8°C in the original carton to protect from light.<sup>3428</sup> The reconstituted solution and the final diluted solution for infusion should be stored at room temperature.<sup>3428</sup> The final diluted solution for infusion should be inspected for particulate matter and discoloration; if either is observed, the vial or bag should be discarded.<sup>3428</sup> Administration of the infusion should begin within 3 hours after reconstitution.<sup>3428</sup>

Because of limited compatibility data, the manufacturer states that other drugs should not be mixed or infused simultaneously with fosnetupitant chloride hydrochloride–palonosetron hydrochloride.<sup>3428</sup> Fosnetupitant chloride hydrochloride–palonosetron hydrochloride is incompatible with any solutions that contain divalent cations (e.g., calcium, magnesium), including Hartmann's solution and Ringer's injection, lactated.<sup>3428</sup>

# Fosphenytoin Sodium

AHFS 28:12.12

## Products

Fosphenytoin is the prodrug for its active metabolite, phenytoin.<sup>3280</sup> Fosphenytoin sodium is available as a solution containing 50 mg phenytoin sodium equivalents (PE)/mL in single-dose 2-mL (100-mg) and 10-mL (500-mg) vials.<sup>3280</sup> Each mL of solution also contains tromethamine (TRIS) buffer along with hydrochloric acid or sodium hydroxide to adjust the pH in water for injection.<sup>3280</sup>

**CAUTION: Care should be taken to avoid confusion between the two different forms (i.e., fosphenytoin sodium and phenytoin sodium) to prevent dosing errors.**<sup>3280</sup>

## Units

Each 1.5 mg of fosphenytoin sodium is equivalent to phenytoin sodium 1 mg and is referred to as 1 mg of phenytoin sodium equivalents (PE).<sup>3280</sup> The amount and concentration of fosphenytoin sodium are expressed in terms of the equivalent mass of phenytoin sodium.<sup>3280</sup> Manufacturers indicate that this avoids the need to perform conversions between the two forms based on molecular weight; however, it necessitates that all prescribing, preparation, and dosing be consistently expressed in terms of PE to avoid dosing errors that could result from confusion between the two forms.<sup>3280</sup>

## pH

From 8.6 to 9<sup>3280</sup> or 8.3 to 9.3.<sup>3281</sup>

## Phosphate Content

Each 1 mg PE contains 0.0037 mmol phosphate.<sup>3280</sup>

## Trade Name(s)

Cerebyx

## Administration

Fosphenytoin sodium is dosed in terms of phenytoin sodium equivalents (PE).<sup>3280</sup>

**CAUTION: Care should be taken to ensure that all prescribing, preparation, and dosing is performed using the correct units and that any confusion between the two forms (i.e., fosphenytoin sodium and phenytoin sodium) is avoided.**<sup>3280</sup>

Fosphenytoin sodium is administered intravenously.<sup>3280</sup> For intravenous infusion, fosphenytoin sodium must be diluted in dextrose 5% or sodium chloride 0.9% to a concentration ranging from 1.5 mg PE/mL to a maximum of 25 mg PE/mL.<sup>3280</sup> The drug also has been administered intramuscularly in certain situations when intravenous access is not possible.<sup>3280</sup>

For the treatment of status epilepticus in adult patients, a loading dose of fosphenytoin sodium should be administered by intravenous infusion at a rate of 100 to 150 mg PE/min; the rate of administration must not exceed 150 mg PE/min.<sup>3280</sup> The intramuscular route of administration generally should not be used in the treatment of status epilepticus.<sup>3280</sup> For non-emergent

situations in adult patients in which fosphenytoin sodium is indicated, the loading dose may be administered intravenously or intramuscularly.<sup>3280</sup> For non-emergent indications, intravenous fosphenytoin sodium infusion should be administered more slowly.<sup>3280</sup> The rate of administration of maintenance doses in adults also should not exceed 150 mg PE/min.<sup>3280</sup>

For the treatment of status epilepticus in pediatric patients, a loading dose of fosphenytoin sodium should be administered by intravenous infusion at a rate of 2 mg PE/kg/min (or 150 mg PE/min, whichever is slower); the rate of administration must not exceed 2 mg PE/kg/min (or 150 mg PE/min, whichever is slower).<sup>3280</sup> For non-emergent indications, intravenous fosphenytoin sodium infusion should be administered more slowly.<sup>3280</sup> For non-emergent situations in pediatric patients in which fosphenytoin sodium is indicated, the loading dose should be administered intravenously at a rate of 1 to 2 mg PE/kg/min (or 150 mg PE/min, whichever is slower).<sup>3280</sup> Following administration of a loading dose, maintenance doses in pediatric patients should be administered at a rate of 1 to 2 mg PE/kg/min (or 100 mg PE/min, whichever is slower).<sup>3280</sup> The intramuscular route of administration generally should not be used in pediatric patients.<sup>3280</sup>

Purple glove syndrome, characterized by edema, discoloration, and pain distal to the site of infusion, has been reported following intravenous administration of fosphenytoin sodium through a peripheral vein and may or may not be associated with extravasation.<sup>3280</sup>

## Stability

Fosphenytoin sodium injection is a clear, colorless to pale yellow solution.<sup>3280</sup> Intact vials should be stored under refrigeration at 2 to 8°C.<sup>3280</sup> Storage at room temperature should not exceed 48 hours.<sup>3280</sup>

Fosphenytoin sodium injection solution should be visually inspected for particulate matter and discoloration prior to administration.<sup>3280</sup> Any unused portions should be discarded.<sup>3280</sup>

## Freezing Solutions

Fosphenytoin sodium (Parke-Davis) 1, 8, and 20 mg PE/mL in dextrose 5% (Baxter) and sodium chloride 0.9% (Baxter) in PVC containers and undiluted fosphenytoin sodium 50 mg PE/mL were packaged in 3-mL polypropylene syringes sealed with tip caps (Becton Dickinson). The samples were frozen at -20°C. Little or no loss occurred after 30 days of frozen storage followed by 7 days at 4 or 25°C. Stability also was maintained if the thawed samples that had been stored at 25°C were returned to the freezer for an additional 7 days.<sup>2083</sup>

## Syringes

Fosphenytoin sodium (Parke-Davis) 50 mg PE/mL was packaged in 3-mL polypropylene syringes with syringe caps (Becton Dickinson) and stored at -20, 4, and 25°C. The samples stored at 4

and 25°C exhibited little or no loss of fosphenytoin sodium in 30 days. The samples stored at –20°C also showed little or no loss of fosphenytoin sodium after 30 days of storage followed by 7

days at 4°C or at 25°C. Stability was maintained if the thawed samples that had been stored at 25°C were returned to the freezer for an additional 7 days.<sup>2083</sup>

## Furosemide

**AHFS 40:28.08**

### Frusemide

## Products

Furosemide is available in 2-, 4-, and 10-mL amber ampuls, single-use vials, prefilled syringes, and syringe cartridges. Each mL of solution contains furosemide 10 mg, water for injection, with sodium chloride for isotonicity, sodium hydroxide, and, if necessary, hydrochloric acid to adjust pH.<sup>1(9/06) 4</sup>

### pH

From 8 to 9.3.<sup>1(9/06) 4</sup>

### Osmolality

Furosemide (Hoechst-Roussel) 10 mg/mL has an osmolality of 287 mOsm/kg.<sup>50</sup> The osmolality of the Elkins-Sinn product has been determined to be 289 mOsm/kg by freezing-point depression.<sup>1071</sup>

In another study, the osmolality of furosemide injection (manufacturer unspecified) was determined to be 291 mOsm/kg.<sup>1233</sup>

### Sodium Content

The injection contains 0.162 mEq of sodium per mL.<sup>4</sup>

### Trade Name(s)

Lasix

## Administration

Furosemide may be administered by intramuscular injection, by direct intravenous injection over 1 to 2 minutes, and by intravenous infusion at a rate not exceeding 4 mg/min.<sup>1(9/06) 4</sup>

## Stability

Exposure to light may cause discoloration; protection from light for the syringes once they are removed from the package is recommended. Do not use furosemide solutions if they have a yellow color. Furosemide products should be stored at controlled room temperature.<sup>1(9/06) 4</sup> Refrigeration may result in precipitation or crystallization. However, resolubilization at room temperature or on warming may be performed without affecting the drug's stability.<sup>593</sup>

Furosemide under simulated summer conditions in paramedic vehicles was exposed to temperatures from 26 to 38°C over 4 weeks. Analysis found no loss of drug under these conditions.<sup>2562</sup>

Furosemide (Hospira) 1 mg/mL diluted in dextrose 5% and packaged as 10 mL in 15-mL polypropylene tubes (BD Biosciences) was physically compatible with less than 4% loss of furosemide in 96 hours at 25°C in the dark.<sup>3568</sup>

### pH Effects

Furosemide is soluble in alkaline solutions and is prepared as a mildly buffered alkaline product.<sup>1(9/06) 4</sup> It can usually be mixed with infusion solutions that are neutral or weakly basic (pH 7 to 10)

and with some weakly acidic solutions that have a low buffer capacity.<sup>4</sup> It should not be mixed with acidic solutions having a pH below 5.5. Solutions such as sodium chloride 0.9%, Ringer's injection, lactated, and dextrose 5% have been recommended. If the solution pH is below 5.5, pH adjustment has been recommended.<sup>1(9/06) 4</sup> In addition, furosemide has been found to be unstable in acidic media,<sup>96 664</sup> but very stable in basic media.<sup>664</sup>

A 2-mL fluid barrier of dextrose 5% in a microbore retrograde infusion set failed to prevent precipitation when used between gentamicin sulfate 5 mg/0.5 mL and furosemide 2 mg/0.2 mL.<sup>1385</sup>

### Autoclaving

Autoclaving of furosemide 1 mg/mL in sodium chloride 0.9% in glass bottles at 115°C for 34 minutes resulted in no loss of furosemide. Storage of the solution for 70 days at room temperature with protection from light also showed no detectable change in furosemide content. However, storage at room temperature with exposure to light for 70 days resulted in about a 60% loss of furosemide and the formation of a yellow-orange precipitate.<sup>1108</sup>

### Light Effects

Furosemide is subject to photodegradation by several mechanisms.<sup>358 400 2067</sup> Photodegradation is minimized at pH 7; rates of decomposition increase as the pH becomes more acidic or basic.<sup>400 2067</sup> Photodegradation is unaffected by ionic strength and initial concentration (in the range of 10 mcg/mL to 1 mg/mL), but the rate of loss may decrease at the higher concentration due to a light-filtering effect of the yellow discoloration. In pH 7 phosphate buffer, more than 60% furosemide loss occurred in transparent glass vials exposed to fluorescent light for 90 hours; little or no loss occurred if the transparent vials were covered with aluminum foil or if amber glass containers were used.<sup>2067</sup>

### Syringes

Furosemide (Hoechst) 10 mg/mL was filled into 25-mL polypropylene syringes (Becton Dickinson) and stored at 25°C while exposed to normal room light or in the dark for 24 hours. There was no detectable change in furosemide content in either light-exposed or light-protected syringes.<sup>1108</sup>

Furosemide (Abbott) 1, 2, 4, and 8 mg/mL diluted in sodium chloride 0.9% was packaged in polypropylene syringes. Samples were stored for 84 days at 22°C and also at 4°C protected from light for 84 days. This was followed by an additional 7 days of storage at 22°C exposed to fluorescent light. No visible changes occurred and little or no loss of furosemide occurred in any of the samples.<sup>2389</sup>

Furosemide 5 mg/mL packaged as 8 mL in 12-mL transparent polypropylene syringes (Terumo) and 50 mL in 60-mL transparent polypropylene syringes (Becton Dickinson) was

physically stable and exhibited little to no loss in 35 days stored at 4°C protected from light followed by 24 hours at 20°C exposed to light.<sup>3569</sup>

### Filtration

Furosemide (Hoechst) 0.04 mg/mL in dextrose 5% and sodium chloride 0.9% was filtered through a 0.22- $\mu$ m cellulose ester membrane filter (Ivex-HP, Millipore) over 6 hours. No significant drug loss due to binding to the filter was noted.<sup>1034</sup>

### Central Venous Catheter

Furosemide (American Regent) 1 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

Sodium chloride 0.9%			200 and 400 mg	5 to 7% loss in 24 hr at 25°C	1348	C
Sodium chloride 0.9%	BA <sup>a</sup>	AB	1.2, 2.4, 3.2 g	Visually compatible. Little loss in 84 days at 4 and 22°C in dark then 7 days at 22°C in fluorescent light	2389	C
Sodium lactate ½ M	BA	HO	600 mg	Physically compatible for 24 hr	315	C

<sup>a</sup> Tested in PVC containers.

### Additive Compatibility

#### Furosemide

Test Drug	Mfr	Conc/L or %	Mfr	Conc/L or %	Test Solution	Remarks	Ref	C/I
Amikacin sulfate	BR	2 g	HO	160 mg	D5W, NS	Transient cloudiness, then visually compatible for 24 hr at 21°C	876	?
Aminophylline	ANT	1 g	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Amiodarone HCl	LZ	1.8 g	ES	200 mg	D5W, NS <sup>a</sup>	Physically compatible. 8% or less amiodarone loss in 24 hr at 24°C in light	1031	C
Amiodarone HCl	LZ	4 g	HO	1 g	D5W	Haze in 5 hr and precipitate in 24 to 72 hr at 30°C. No changes at 15°C	1479	I

**Additive Compatibility (Cont.)**

Test Drug	Mfr	Conc/L or %	Mfr	Conc/L or %	Test Solution	Remarks	Ref	C/I
Ampicillin sodium	BE	20 g	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Atropine sulfate	ANT	60 mg	HO	1 g	W	Physically compatible for 72 hr at 15 and 30°C	1479	C
Bumetanide	LEO	6 mg	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Buprenorphine HCl		75 mg	HO	1 g	W	Haze for 6 hr at 30°C. No change at 15°C	1479	I
Calcium gluconate	ANT	2 g	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Cefuroxime sodium	GL	37.5 g	HO	1 g	W	Physically compatible for 72 hr at 15 and 30°C	1479	C
Chlorothiazide sodium	APP	10 g	HOS	1 g	D5W <sup>d</sup>	Physically compatible with less than 10% loss of either drug for 96 hours at 25°C in the dark	3568	C
Chlorpromazine HCl	ANT	5 g	HO	1 g	W	Precipitates immediately	1479	I
Cloxacillin sodium	BE	20 g	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Conivaptan HCl	BA					Stated to be incompatible	2838	I
Dexamethasone sodium phosphate	MSD	4 g	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Diamorphine HCl	EV	500 mg	HO	1 g	W	Physically compatible for 72 hr at 15 and 30°C	1479	C
Diazepam	PHX	1 g	HO	1 g	D5W	Precipitates immediately	1479	I
Digoxin	BW	25 mg	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Dobutamine HCl	LI	1 g	HO	1 g	D5W, NS	Cloudy in 1 hr at 25°C	789	I
Dobutamine HCl	LI	1 g	WY	5 g	D5W, NS	Immediate white precipitate	812	I
Dobutamine HCl	LI	500 mg	HO	1 g	NS	Haze forms immediately	1479	I
Doxapram HCl	WW					Precipitation or gas formation	3220	I
Epinephrine HCl	ANT	8 mg	HO	1 g	W	Physically compatible for 72 hr at 15 and 30°C	1479	C
Eptifibatide	ME	750 mg		10 g		Precipitation and crystallization occurred after 1 hr	3049	I
Erythromycin lactobionate	AB	5 g	HO	1 g	NS	Precipitates immediately. Crystals form in 12 to 24 hr at 15 and 30°C	1479	I
Gentamicin sulfate	SC	1.6 g	HO	800 mg	D5W, NS	Furosemide precipitates immediately	876	I
Gentamicin sulfate	RS	8 g	HO	1 g	NS	Physically compatible for 24 hr at 15 and 30°C. Precipitate forms in 48 to 72 hr	1479	C
Heparin sodium	WED	20,000 units	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Hydrocortisone sodium succinate		1 g		200 and 400 mg	D5W, NS	6 to 8% hydrocortisone loss and 5 to 6% furosemide loss in 24 hr at 25°C	1348	C
Hydrocortisone sodium succinate		300 mg		200 and 400 mg	D5W, NS	6 to 8% hydrocortisone loss in 6 hr and 10 to 14% loss in 24 hr at 25°C. 5 to 6% furosemide loss in 24 hr	1348	I
Hydrocortisone sodium succinate	UP	50 g	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Isoproterenol HCl	PX	4 mg	HO	1 g	D5W	Precipitates immediately	1479	I
Isosorbide dinitrate		1 g	HO	1 g		Physically compatible for 72 hr at 15 and 30°C	1479	C
Lidocaine HCl	ANT	2 g	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Mannitol	BA <sup>c</sup>	20%	AB	200, 400, 800 mg		Visually compatible for 72 hr at 22°C	1803	C

**Additive Compatibility (Cont.)**

Test Drug	Mfr	Conc/L or %	Mfr	Conc/L or %	Test Solution	Remarks	Ref	C/I
Meperidine HCl	RC	5 g	HO	1 g	W	Fine precipitate forms immediately	1479	I
Meropenem	ZEN	1 and 20 g	HO	1 g	NS	Visually compatible for 4 hr at room temperature	1994	C
Metoclopramide HCl	ANT	1 g	HO	1 g	NS	Precipitates immediately	1479	I
Midazolam HCl	RC	50 and 250 mg		80 mg	NS	Visually compatible for 4 hr	355	C
Morphine sulfate	EV	1 g	HO	1 g	W	Physically compatible for 72 hr at 15 and 30°C	1479	C
Nitroglycerin	ACC	400 mg	HO	1 g	D5W <sup>b</sup>	Physically compatible with no nitroglycerin loss in 48 hr at 23°C. Furosemide not tested	929	C
Nitroglycerin	ACC	400 mg	HO	1 g	NS <sup>b</sup>	Physically compatible with 3% nitroglycerin loss in 48 hr at 23°C. Furosemide not tested	929	C
Potassium chloride	ANT	40 mmol	HO	1 g	W	Physically compatible for 72 hr at 15 and 30°C	1479	C
Prochlorperazine edisylate	MB	1.25 g	HO	1 g	W	Yellow precipitate forms immediately	1479	I
Promethazine HCl	MB	5 g	HO	1 g	W	White precipitate forms immediately	1479	I
Ranitidine HCl	GL	500 mg	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Ranitidine HCl	GL	50 mg and 2 g		400 mg	D5W	Physically compatible. Ranitidine stable for 24 hr at 25°C. Furosemide not tested	1515	C
Scopolamine butylbromide	BI	2 g	HO	1 g	W	Physically compatible for 72 hr at 15 and 30°C	1479	C
Sodium bicarbonate	IMS	8.4%	HO	1 g		Physically compatible for 72 hr at 15 and 30°C	1479	C
Theophylline		2 g		330 mg	D5W	Visually compatible. Little theophylline and 10% furosemide loss in 48 hr	1909	C
Tobramycin sulfate	DI	1.6 g	HO	800 mg	D5W, NS	Transient cloudiness then physically compatible for 24 hr at 21°C	876	?
Tobramycin sulfate	LI	8 g	HO	1 g	NS	Physically compatible for 72 hr at 15 and 30°C	1479	C
Verapamil HCl	KN	80 mg	HO	200 mg	D5W, NS	Physically compatible for 24 hr	764	C
Verapamil HCl	AB	500 mg	HO	1 g	NS	Slight precipitate forms but dissipates	1479	?

<sup>a</sup> Tested in both polyolefin and PVC containers.

<sup>b</sup> Tested in glass containers.

<sup>c</sup> Tested in PVC containers.

<sup>d</sup> Tested in polypropylene containers.

## Fusidate Sodium

AHFS 8:12.28.92

### Products

Fusidate sodium is available as a dry powder in vials containing 500 mg (equivalent to 480 mg of fusidic acid). It is packaged with a diluent vial containing 10 mL of phosphate–citrate buffer (pH 7.4 to 7.6). The drug should be reconstituted with the diluent and diluted further with sodium chloride 0.9% or other compatible diluent for administration.<sup>38</sup>

### Sodium and Phosphate Content

Each vial of fusidate sodium contains 3.1 mmol of sodium and 1.1 mmol of phosphate.<sup>38</sup>

### Trade Name(s)

Fucidin

### Administration

Fusidate sodium is administered by slow intravenous infusion over not less than six hours if a superficial vein is employed. If a central venous line is used, the infusion should be given over two to four hours. The reconstituted fusidate sodium in 10 mL of buffer solution is diluted in 500 mL of sodium chloride 0.9% or other compatible infusion solution for administration. The drug must not be given by other routes.<sup>38</sup>

### Stability

Fusidate sodium should be stored below 25°C and protected from light. Reconstituted solutions that are added to 500 mL of compatible infusion solutions are stable for 24 hours at room temperature. Unused portions of the reconstituted solution should be discarded.<sup>38</sup>

Fusidate sodium reconstituted with the buffer solution to 50 mg/mL is physically incompatible with infusion solutions containing amino acids solutions, dextrose 20% or greater, and lipid infusions.<sup>38</sup>

Fusidate sodium (Leo) at a concentration of 0.125 mg/mL is stated to be physically incompatible with the following peritoneal dialysis solutions<sup>1800</sup>:

- Dianeal PD2 with dextrose 1.36%
- Dianeal PD3 with dextrose 1.36%
- Dianeal with dextrose 3.86%
- Peritoneal Dialysis Solution 6.36%
- Peritoneal Dialysis Solution 6.36% + acetate
- Peritoneal Dialysis Solution with dextrose 2.27%

### pH Effects

Precipitation may occur upon dilution if the resulting pH is less than 7.4.<sup>38</sup>

### Freezing Solutions

Fusidate sodium (Leo) 1 mg/mL in sodium chloride 0.9% and dextrose 5% is stated to be stable frozen at –20°C for 24 hours followed by thawing in a microwave oven.<sup>1800</sup>

Fusidic acid (Leo) 500 mg, reconstituted in buffer and diluted to 550 mL in sodium chloride 0.9% in PVC bags, was stored frozen at –20°C. No loss was found after 12 months of storage followed by microwave thawing. Furthermore, the solution was physically compatible, with no increase in subvisible particles. In addition, there was no loss of fusidate sodium after six months of storage at –20°C followed by three freeze–thaw cycles.<sup>1612</sup>

## Gallium Nitrate

AHFS 92:24

### Products

Gallium nitrate is available in 20-mL vials. Each mL of solution contains gallium nitrate 25 mg, sodium citrate dihydrate 28.75 mg, and sodium hydroxide or hydrochloric acid for pH adjustment during manufacturing in water for injection.<sup>1(2/08)</sup>

### pH

From 6 to 7.<sup>1(2/08)</sup>

### Trade Name(s)

Ganite

### Administration

Gallium nitrate is administered by intravenous infusion over 24 hours after dilution in 1000 mL of dextrose 5% or sodium chloride 0.9%.<sup>1(2/08)</sup>

### Stability

Gallium nitrate in intact vials should be stored at controlled room temperature. The manufacturer states that unused portions of the vials should be discarded because no preservative is present.<sup>1(2/08)</sup>

Gallium nitrate diluted in 1000 mL of dextrose 5% or sodium chloride 0.9% is stable for 48 hours at room temperature and for 7 days stored under refrigeration.<sup>1(2/08)</sup>

# Ganciclovir Sodium

**AHFS 8:18.32**

## Products

Ganciclovir sodium is available as a lyophilized powder in single-dose vials containing the equivalent of 500 mg of ganciclovir.<sup>3361 3366</sup>

Vials also may include hydrochloric acid and sodium hydroxide to adjust the pH.<sup>3361</sup> Each vial should be reconstituted with 10 mL of sterile water for injection and swirled gently or shaken to fully wet the product and dissolve the drug to yield a 50-mg/mL solution of ganciclovir.<sup>3361 3366</sup> Paraben-containing diluents (e.g., bacteriostatic water for injection containing parabens) should not be used to reconstitute ganciclovir sodium because precipitation may result.<sup>3361</sup>

<sup>3366</sup> Reconstituted solutions should be visually inspected for particulate matter and discoloration prior to dilution; if particulate matter is present or discoloration occurs, the vial should be discarded.<sup>3361</sup>

<sup>3366</sup> The appropriate volume of the reconstituted solution should be withdrawn from the vial and diluted in an appropriate volume (usually 100 mL) of sodium chloride 0.9%, dextrose 5%, Ringer's injection, or Ringer's injection, lactated to obtain a ganciclovir concentration of 10 mg/mL or less prior to administration; concentrations greater than 10 mg/mL are not recommended.<sup>3361 3366</sup>

Ganciclovir also is available as a 2-mg/mL premixed, ready-to-use solution in 250-mL single-dose (preservative-free) bags containing 500 mg of ganciclovir; this product does not contain the sodium salt of ganciclovir.<sup>3362</sup> Each mL also contains sodium chloride 8 mg in water for injection and may contain sodium hydroxide and/or hydrochloric acid to adjust the pH.<sup>3362</sup> Solutions should be visually inspected for particulate matter and discoloration prior to administration.<sup>3362</sup>

## pH

Ganciclovir 50-mg/mL solution (reconstituted from ganciclovir sodium) has a pH of 11.<sup>3361 3366</sup>

Ganciclovir 2-mg/mL premixed, ready-to-use solution has a pH of 7.5.<sup>3362</sup>

## Sodium Content

Each 500-mg vial of ganciclovir sodium (Par) contains 46 mg of sodium.<sup>3366</sup>

## Trade Name(s)

Cytovene-IV

## Administration

Solutions of ganciclovir must be administered only by intravenous infusion at a constant rate over 1 hour.<sup>3361 3362 3366</sup> The recommended infusion rate should not be exceeded.<sup>3361 3362 3366</sup>

The drug should *not* be administered by intramuscular, subcutaneous, or rapid or bolus intravenous injection.<sup>3361 3362 3366</sup> Intramuscular or subcutaneous administration can result in severe tissue irritation due to the high pH of the drug; rapid or bolus intravenous injection can increase the risk of toxicity.<sup>3361 3366</sup>

Administration of ganciclovir should be accompanied by adequate hydration.<sup>3361 3362 3366</sup> The drug must only be infused

into a vein with adequate blood flow, preferably through a plastic cannula, to permit rapid dilution and distribution of the drug in an attempt to avoid phlebitis and/or pain at the infusion site.<sup>3361 3362 3366</sup> Phlebitis and/or pain at the site of intravenous infusion still may occur despite further dilution of the reconstituted solution of the drug in intravenous infusion solutions.<sup>3366</sup>

As with other toxic drugs, caution should be exercised in the handling and preparation of ganciclovir.<sup>3361 3362 3366</sup> Direct contact of the drug with the skin or mucous membrane should be avoided, and the use of disposable gloves during handling has been recommended.<sup>3361 3366</sup> If skin or mucosal membrane contact with the solution occurs, the exposed area should be washed thoroughly with soap and water; for eye contact, the eyes should be flushed thoroughly with water.<sup>3361 3366</sup> Procedures and guidelines for the proper disposal of ganciclovir should be considered.<sup>3361 3362 3366</sup>

## Stability

Ganciclovir sodium is a white to off-white powder that forms a clear solution upon reconstitution.<sup>3361 3366</sup> Intact vials should be stored at controlled room temperature.<sup>3361 3366</sup> The reconstituted solution is stable in the vial for 12 hours at room temperature (25°C).<sup>3361 3366</sup> Manufacturers do not recommend refrigeration of the reconstituted solution;<sup>3361 3366</sup> however, ganciclovir 500 mg/10 mL in sterile water for injection had no significant loss in 60 days when stored at 4°C.<sup>1637</sup> One manufacturer states that diluted solutions of ganciclovir may be stored at 2 to 8°C for up to 24 hours.<sup>3361</sup> Neither reconstituted nor diluted solutions of ganciclovir should be frozen.<sup>3361 3362</sup>

Ganciclovir premixed, ready-to-use solution is clear and colorless.<sup>3362</sup> Intact containers should be stored at controlled room temperature.<sup>3362</sup> Crystals may form during transportation or storage at temperatures that are lower than those recommended for storage.<sup>3362</sup> Bags should be gently shaken to redissolve such crystals.<sup>3362</sup> The solution must be clear at the time of use.<sup>3362</sup> Any unused portion should be discarded.<sup>3362</sup>

Ganciclovir sodium (Syntex) 0.35 mg/mL diluted in sodium chloride 0.9% and stored at 22°C did not exhibit a substantial antimicrobial effect on the growth of 4 organisms (*Enterococcus faecium*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Candida albicans*) inoculated into the solution. *S. aureus* and *C. albicans* remained viable for 24 hours, and the others remained viable to the end of the study at 120 hours. The author recommended that diluted solutions of ganciclovir be stored under refrigeration whenever possible and that the potential for microbiological growth should be considered when assigning expiration periods.<sup>2160</sup>

## Freezing Solutions

The manufacturers do not recommend freezing reconstituted and/or diluted solutions of ganciclovir,<sup>3361 3362</sup> however, ganciclovir sodium (Syntex), prepared at a ganciclovir concentration of 1.4, 4, and 7 mg/mL in sodium chloride 0.9% packaged in polypropylene syringes and 0.28 and 1.4 mg/mL in sodium chloride 0.9%

packaged in polyvinyl chloride (PVC) containers was evaluated. All samples exhibited 4% or less drug loss after 364 days at  $-20^{\circ}\text{C}$ .<sup>1836</sup>

No ganciclovir loss occurred in a 10-mg/mL solution in sodium chloride 0.9% in 48 weeks when stored frozen at  $-8^{\circ}\text{C}$ .<sup>2595</sup>

### Syringes

Ganciclovir sodium (Syntex), prepared at a ganciclovir concentration of 5.8 mg/mL in sodium chloride 0.9%, packaged in polypropylene infusion-pump syringes (Healthtek), exhibited 3% or less drug loss in 10 days at  $4^{\circ}\text{C}$  and no loss in 12 hours at  $25^{\circ}\text{C}$ .<sup>1742</sup>

Ganciclovir sodium (Syntex), prepared at a ganciclovir concentration of 1.4, 4, and 7 mg/mL in sodium chloride 0.9% was packaged in polypropylene syringes and stored at  $20^{\circ}\text{C}$ ,  $4^{\circ}\text{C}$ , and  $-20^{\circ}\text{C}$ . Drug loss of 4% or less occurred in 7 days at  $20^{\circ}\text{C}$ , in 80 days at  $4^{\circ}\text{C}$ , and in 364 days at  $-20^{\circ}\text{C}$ .<sup>1836</sup>

Ganciclovir sodium (Roche), prepared at a ganciclovir concentration of 5 mg/mL in sodium chloride 0.9% packaged as 20 mL in 50-mL polypropylene syringes (Becton Dickinson) and protected from light remained stable and clear for up to 185 days at  $23$  to  $27^{\circ}\text{C}$  and 2 to  $8^{\circ}\text{C}$ .<sup>3363</sup>

### Central Venous Catheter

Ganciclovir sodium (Roche), prepared at a ganciclovir concentration of 5 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

# Gemcitabine Hydrochloride

## AHFS 10:00

### Products

Gemcitabine hydrochloride is available as a lyophilized powder in single-dose (preservative-free) vials containing 200 mg, 1 g, or 2 g of drug (as the base).<sup>3526 3527</sup> For each 200 mg of gemcitabine lyophilized powder contained in each vial, mannitol 200 mg and sodium acetate 12.5 mg also are present.<sup>3526 3527</sup> The contents of the 200-mg, 1-g, and 2-g vials should be reconstituted with 5, 25, and 50 mL, respectively, of sodium chloride 0.9% and shaken to dissolve the powder to yield a solution with a gemcitabine concentration of 38 mg/mL.<sup>3526 3527</sup> Prior to administration, the appropriate dose of the reconstituted solution should be diluted with sodium chloride 0.9% to a final gemcitabine concentration of not less than 0.1 mg/mL.<sup>3526 3527</sup>

Gemcitabine hydrochloride also is available as a concentrate for injection.<sup>3528 3529</sup> In 200-mg, 1-g, and 2-g single-dose vials, each mL of the concentrate contains 38 mg of gemcitabine in water for injection.<sup>3529</sup> In 200-mg and 1-, 1.5-, and 2-g multidose vials, each mL of the concentrate for injection contains 100 mg of gemcitabine, 250 mg of polyethylene glycol (PEG) 300, 150 mg of propylene glycol, and 16 mg of sodium hydroxide in dehydrated alcohol.<sup>3528</sup> Prior to administration, the appropriate dose of the concentrate for injection must be diluted with sodium chloride 0.9% to a final gemcitabine concentration of not less than 0.1 mg/mL.<sup>3528 3529</sup> The diluted solution should be mixed by gentle inversion and should not be shaken.<sup>3528</sup>

Gemcitabine hydrochloride also is available as a premixed, ready-to-use solution for infusion in single-dose bags containing 120, 130, 140, 150, 160, 170, 180, 190, 200, and 220 mL.<sup>3530</sup> Each 100 mL of the ready-to-use solution for infusion contains 1 g of gemcitabine and 900 mg of sodium chloride in water for injection.<sup>3530</sup> The ready-to-use solution for infusion should not be further diluted and should *not* be used in patients requiring less than the entire dose of a single-dose bag.<sup>3530</sup>

The pH of all of the gemcitabine products may have been adjusted by the manufacturers with sodium hydroxide and/or hydrochloric acid.<sup>3526 3527 3528 3529 3530</sup>

Solutions of gemcitabine (e.g., reconstituted solutions, commercially available solutions, solutions diluted for infusion, commercially available solutions for infusion) should be inspected for particulate matter and discoloration prior to administration; if particulate matter is present or discoloration has occurred, solutions should be discarded.<sup>3526 3527 3528 3529 3530</sup>

### Equivalency

Gemcitabine hydrochloride 113.85 mg is equivalent to 100 mg of gemcitabine base.<sup>3527 3528 3529 3530</sup>

### Trade Name(s)

Gemzar, Infugem

### Administration

Gemcitabine hydrochloride is administered by intravenous infusion over 30 minutes.<sup>3526 3527 3528 3529 3530</sup> When 2 bags of the premixed, ready-to-use solution for infusion are required to achieve the appropriate dose, the combined volume of both infusion bags should be infused over 30 minutes.<sup>3530</sup> Prolongation of the infusion time of gemcitabine hydrochloride beyond 60 minutes has resulted in an increased incidence of adverse effects.<sup>3526 3527 3528 3529 3530</sup>

As with other toxic drugs, caution should be exercised in the handling and preparation of gemcitabine hydrochloride and applicable special handling and disposal procedures should be followed.<sup>3526 3527 3528 3529 3530</sup> Gloves are recommended to be worn in the preparation of the drug.<sup>3526 3527 3528 3529 3530</sup> If skin or mucosal contact with the drug occurs, the affected area(s) should be washed immediately and thoroughly with copious amounts of water.<sup>3526 3527 3528 3529 3530</sup>

### Stability

Gemcitabine hydrochloride is a white to off-white lyophilized powder that forms a clear, colorless to light straw-colored solution upon reconstitution.<sup>3526 3527</sup> Intact vials of gemcitabine hydrochloride should be stored at controlled room temperature.<sup>3526 3527</sup> Manufacturers state that reconstituted and diluted solutions for infusion prepared from the lyophilized powder may be stored at controlled room temperature for up to 24 hours; solutions not used within 24 hours after reconstitution should be discarded.<sup>3526 3527</sup> However, other information indicates the reconstituted solution may be stable for longer periods.<sup>2227</sup> (See Reconstituted Solutions). Manufacturers state that reconstituted and diluted solutions of gemcitabine hydrochloride should not be refrigerated because crystallization may occur.<sup>3526 3527</sup>

Gemcitabine hydrochloride concentrate for injection is a clear, colorless to pale yellow<sup>3528</sup> or light straw-colored<sup>3529</sup> solution. Intact multidose vials of gemcitabine hydrochloride concentrate for injection should be stored at controlled room temperature.<sup>3528</sup> Multidose vials are stable for up to 28 days from initial vial puncture when stored at room temperature.<sup>3528</sup> Intact single-dose vials of gemcitabine hydrochloride concentrate for injection should be stored at 2 to 8°C and should not be frozen.<sup>3529</sup> Manufacturers state that diluted solutions for infusion prepared from the concentrate for injection may be stored at controlled room temperature for up to 24 hours; solutions not used within 24 hours after dilution should be discarded.<sup>3528 3529</sup>

Gemcitabine hydrochloride premixed, ready-to-use solution for infusion is a clear, colorless solution.<sup>3530</sup> Intact containers should be stored at controlled room temperature.<sup>3530</sup> The solution should not be frozen because crystallization may occur.<sup>3530</sup>

Gemcitabine hydrochloride (Lilly) 2.4 mg/mL diluted in sodium chloride 0.9% and stored at 22°C did not exhibit a substantial antimicrobial effect on the growth of 4 organisms (*Enterococcus faecium*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Candida albicans*) inoculated into the solution. *C. albicans* maintained viability for 120 hours, and the others were viable for 24 hours. The author recommended that diluted solutions of gemcitabine hydrochloride be stored under refrigeration whenever possible and that the potential for microbiological growth should be considered when assigning expiration periods.<sup>2160</sup>

### Reconstituted Solutions

The contents of gemcitabine hydrochloride (Lilly) 200-mg and 1-g vials were reconstituted to a gemcitabine concentration of 38 mg/mL with sterile water for injection and also sodium chloride 0.9% in the original vials and evaluated over periods of 35 days at 23°C exposed to and protected from fluorescent light and at 4°C protected from light.<sup>2227</sup> The samples stored at 23°C were physically stable throughout the study period.<sup>2227</sup> Under 4% loss occurred in 35 days at 23°C.<sup>2227</sup> When refrigerated, the solutions remained physically and chemically stable for at least 7 days, but large colorless crystals formed in some samples after that time.<sup>2227</sup> The crystals did not redissolve on warming to room temperature.<sup>2227</sup> No loss occurred in the refrigerated solutions unless crystals formed; gemcitabine losses of 20 to 35%

were determined in samples containing crystals.<sup>2227</sup> Exposure to or protection from fluorescent light did not affect gemcitabine stability.<sup>2227</sup>

### Syringes

Gemcitabine hydrochloride (Lilly) 38 mg/mL in sodium chloride 0.9% was repackaged as 10 mL of solution in 20-mL plastic syringes (Becton Dickinson) and sealed with tip caps (Red Cap, Burron).<sup>2227</sup> Sample syringes were stored at 23°C both exposed to and protected from fluorescent light and at 4°C protected from light for 35 days.<sup>2227</sup> All samples were physically stable throughout the study period.<sup>2227</sup> Although not observed in the solutions packaged in plastic syringes in this study,<sup>2227</sup> crystallization can occur in reconstituted solutions stored under refrigeration.<sup>3526 3527</sup> Little to no loss occurred in 35 days under any of the conditions.<sup>2227</sup>

### Sorption

Gemcitabine hydrochloride has not exhibited any incompatibilities with bottles or polyvinyl chloride (PVC) bags and administration sets.<sup>3526 3527 3528 3529</sup>

Gemcitabine hydrochloride (Lilly) 5.12 mg/mL in sodium chloride 0.9% exhibited no loss due to sorption in polyethylene and PVC containers compared to glass containers over 48 hours at room temperature.<sup>2420 2430</sup>

## Compatibility Information

### Solution Compatibility

#### Gemcitabine HCl

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 5%	BA <sup>a</sup>	LI	0.1 and 10 g	Physically compatible and chemically stable with little to no loss in 35 days at 23°C in light and dark and at 4°C in dark	2227	C
Dextrose 5%	BA <sup>a</sup>	LI	0.1, 10, and 38 g	Physically compatible and chemically stable with no loss in 7 days at 32°C in dark	2227	C
Sodium chloride 0.9%	BA <sup>a</sup>	LI	0.1 and 10 g	Physically compatible and chemically stable with little to no loss in 35 days at 23°C in light and dark and at 4°C in dark	2227	C
Sodium chloride 0.9%	BA <sup>a</sup>	LI	0.1, 10, and 38 g	Physically compatible and chemically stable with little to no loss in 7 days at 32°C in dark	2227	C
Sodium chloride 0.9%	GRI <sup>a b</sup>	LI	7.5 and 25 g	Visually compatible. Under 4% loss in 27 days at 25°C in light and dark	2741	C

<sup>a</sup> Tested in PVC containers.

<sup>b</sup> Tested in glass containers.

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>d</sup> Ampicillin component. Ampicillin in a 2:1 fixed-ratio concentration with sulbactam.

<sup>e</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>f</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>g</sup> Not specified whether concentration refers to single component or combined components.

## Gentamicin Sulfate

### AHFS 8:12.02

#### Products

Gentamicin (as the sulfate) is available at a concentration of 40 mg/mL in 2- and 20-mL vials. The drug is also available at a concentration of 10 mg/mL for pediatric use. The products also may contain edetate disodium, sodium bisulfite, and parabens.<sup>1(10/04) 4</sup>

Gentamicin sulfate also is available from several manufacturers premixed in various concentrations in sodium chloride 0.9%.<sup>4</sup>

#### pH

The injection for intravenous or intramuscular administration has a pH of 3 to 5.5. Premixed infusions of gentamicin sulfate in sodium chloride 0.9% have a pH of around 4 to 4.5.<sup>4</sup>

#### Osmolality

Gentamicin sulfate (Wyeth) 40 mg/mL has an osmolality of 160 mOsm/kg.<sup>50</sup> Gentamicin sulfate pediatric injection (Elkins-Sinn) 10 mg/mL has an osmolality of 116 mOsm/kg by freezing-point depression or 212 mOsm/kg by vapor pressure.<sup>1071</sup>

The osmolality of gentamicin sulfate 1 mg/mL was 262 mOsm/kg in dextrose 5% and 278 mOsm/kg in sodium chloride 0.9%. At a 2.5-mg/mL concentration, the osmolality was 278 mOsm/kg in dextrose 5% and 293 mOsm/kg in sodium chloride 0.9%.<sup>1375</sup>

The osmolality of gentamicin sulfate 80 mg was calculated for the following dilutions:<sup>1054</sup>

Diluent	Osmolality (mOsm/kg)	
	50 mL	100 mL
Dextrose 5%	293	285
Sodium chloride 0.9%	320	315

#### Osmolarity

The osmolarity of the premixed infusions in sodium chloride 0.9% is approximately 284 to 308 mOsm/L.<sup>4</sup>

#### Administration

Gentamicin sulfate is administered by intramuscular injection or intermittent intravenous infusion over 0.5 to 2 hours. For adults, intravenous administration in 50 to 200 mL of sodium chloride 0.9% or dextrose 5% is recommended, while the volume for pediatric patients should be reduced to meet patients' needs.<sup>1(10/04) 4</sup>

#### Stability

Gentamicin sulfate injection is colorless to slightly yellow.<sup>4</sup> Intact containers should be stored at controlled room temperature and protected from freezing.<sup>1(10/04) 4</sup> Drug concentration

is unrelated to color intensity of gentamicin sulfate solutions.<sup>2139</sup>

#### Freezing Solutions

Gentamicin sulfate (Schering) 50 mg in 50 mL of dextrose 5% and also sodium chloride 0.9% in polyvinyl chloride (PVC) containers frozen at  $-20^{\circ}\text{C}$  was stable for 30 days.<sup>299</sup>

Gentamicin sulfate (Schering) 80 mg/100 mL of dextrose 5% in PVC bags was frozen at  $-20^{\circ}\text{C}$  for 30 days and then thawed by exposure to ambient temperature or microwave radiation. No precipitation or color change was observed, and no drug loss occurred. Subsequent storage of the admixture at room temperature for 24 hours also yielded a physically compatible solution, exhibiting little or no drug loss.<sup>554</sup>

Gentamicin sulfate (Elkins-Sinn) 120 mg/50 mL lost 6% in dextrose 5% and 2% in sodium chloride 0.9% in 28 days when frozen at  $-20^{\circ}\text{C}$ .<sup>981</sup>

The stability of gentamicin sulfate (Schering) 5.45 mg/mL in dextrose 5% frozen in an ambulatory pump reservoir was studied. The drug-filled reservoirs were stored at  $-20^{\circ}\text{C}$  for 30 days and then thawed at  $5^{\circ}\text{C}$  for 4 days. This thawing was then followed by 2 days of drug delivery through the pump at  $37^{\circ}\text{C}$ . No visible changes and no loss occurred during storage and delivery. Furthermore, plasticizer diethylhexyl phthalate (DEHP) levels were insignificant.<sup>1490</sup>

#### Syringes

The stability of gentamicin sulfate (Schering) repackaged in plastic syringes (Monoject) was significantly less than in glass syringes (Glaspak, Becton Dickinson) at both 4 and  $25^{\circ}\text{C}$ . The commercial concentrations were tested in the following amounts: 40 mg/mL—1, 0.75, 0.5, and 0.25 mL; and 10 mg/mL—1.5, 1, and 0.5 mL. Storage in plastic syringes resulted in an average loss of 16% in 30 days and in the formation of a brown precipitate. In glass syringes, the average loss was 7% at 30 days. The brown precipitate did not appear after 30 days but was present at 60 days. It appeared in the cannula of the needle in both glass and plastic syringes. For the 40-mg/mL concentration, the volume of the sample also affected stability. Significantly less loss was noted in the smaller volumes (0.25 and 0.5 mL) than in the larger volumes (0.5 and 1 mL). This volume-related phenomenon was not demonstrated in the 10-mg/mL pediatric concentration. Storage temperature had no effect on stability over 90 days.<sup>297</sup>

The manufacturer also expressed concern about plastic packaging of gentamicin, noting a possibly inadequate oxygen and moisture barrier both through the tip and the walls of the syringe. It was indicated that gentamicin is oxygen sensitive and that depletion of the antioxidant present could result in instability. Further, loss of moisture at the tip could result in occlusion by the dried product.<sup>403</sup>

Gentamicin sulfate 40 mg/1 mL was packaged in polypropylene syringes (Plastipak, Becton Dickinson). No significant change in concentration occurred over 30 days at 4 or 25°C.<sup>401</sup>

Gentamicin sulfate (Elkins-Sinn) 120 mg, diluted with 1 mL of sodium chloride 0.9% to a final volume of 4 mL, was stable (less than 10% loss) when stored in polypropylene syringes (Becton Dickinson) for 48 hours at 23°C under fluorescent light.<sup>1159</sup>

The stability of gentamicin sulfate (Elkins-Sinn) diluted to 10 mg/mL with sodium chloride 0.9% and stored in glass syringes (Becton Dickinson) at 4°C was studied. No loss of gentamicin sulfate was found during 12 weeks of storage.<sup>1265</sup>

### Sorption

Gentamicin sulfate was shown not to exhibit sorption to PVC bags and tubing, polyethylene bags and tubing, multilayer bags of polyethylene, polyamide, and polypropylene, Silastic tubing, polypropylene syringes, and elastomeric reservoirs.<sup>536 606 2014 2269</sup>

### Filtration

The effect of several filters on the delivered concentration of gentamicin sulfate (Roussel) from simulated pediatric infusions was studied. A syringe containing dextrose 10% on a syringe pump set at 8.26 mL/hr was connected by intravenous tubing to a 0.5- $\mu$ m air-blocking filter set (Travenol), a 0.22- $\mu$ m air-eliminating filter set (Travenol), and a 0.2- $\mu$ m air-eliminating filter set (Pall). Gentamicin doses of 2.5 and 7.5 mg were injected antegrade to the filter. The effluents were sampled at 1, 1.5, 2, and 4 hours. No significant drug sorption to the plastic tubing or inline filters occurred. However, because of the difference in specific gravity of the drug (1.010) and intravenous solution (1.032), variations in delivered gentamicin did occur due to filter design and position. With the Travenol filters, gentamicin delivery was more rapid with ascending flow in both horizontal and vertical positions. Drug delivery was significantly delayed with descending flow in both positions. The Pall filter delivered gentamicin more rapidly in the horizontal position with either

ascending or descending flow. The vertical filter position significantly delayed drug delivery in both flow directions.<sup>804</sup>

However, in another study, gentamicin sulfate 60 mg/15 mL was injected as a bolus through a 0.2- $\mu$ m nylon air-eliminating filter (Ultipor, Pall) to evaluate the effect of filtration on simulated intravenous push delivery. About 38% of the drug was delivered through the filter after flushing with 10 mL of sodium chloride 0.9%.<sup>809</sup>

Gentamicin sulfate 5 and 10 mg/55 mL of dextrose 5% and sodium chloride 0.9% was filtered over 20 minutes through a 0.22- $\mu$ m cellulose ester filter set (Ivex-2, Millipore). Virtually all of the drug was delivered through the filter.<sup>1003</sup>

The binding of gentamicin sulfate to the filter of a set used for continuous ambulatory peritoneal dialysis (CAPD) was studied. Gentamicin sulfate 60 mg/2 L in Dianeal 137 with dextrose 4.25 and 1.5% was filtered through a Peridex CAPD filter set (Millipore); this set has a surface area 27 times larger than an inline intravenous filter. About 25% binding occurred from the solution containing dextrose 4.25%, but only 7.5% was bound with the 1.5% solution.<sup>1112</sup>

Gentamicin sulfate (Unicet-Unilabo) 0.32 mg/mL in dextrose 5% and sodium chloride 0.9% was filtered through a 0.22- $\mu$ m cellulose ester membrane filter (Ivex-HP, Millipore) over 6 hours. No significant drug loss due to binding to the filter was noted.<sup>1034</sup>

### Central Venous Catheter

Gentamicin sulfate (Fujisawa) 1 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

### Solution Compatibility

#### Gentamicin sulfate

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Amino acids 4.25%, dextrose 25%	MG	SC	80 mg	No increase in particulate matter in 24 hr at 5°C	349	C

## Y-Site Injection Compatibility (1:1 Mixture) (Cont.)

- <sup>a</sup> Tested in dextrose 5%.
- <sup>b</sup> Tested in sodium chloride 0.9%.
- <sup>c</sup> Tested in both dextrose 5% and sodium chloride 0.9%.
- <sup>d</sup> Tested in dextrose 5%, Ringer's injection, lactated, sodium chloride 0.45%, and sodium chloride 0.9%.
- <sup>e</sup> Tested in sodium chloride 0.45%.
- <sup>f</sup> Tested in dextrose 5% with albumin human 2 mg/mL.
- <sup>g</sup> Tested in sterile water for injection.
- <sup>h</sup> Lyophilized formulation tested.
- <sup>i</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.
- <sup>j</sup> A 32.5-mL sample of parenteral nutrition solution mixed with 50 mL of antibiotic solution.
- <sup>k</sup> Run at 21 mL/hr.
- <sup>l</sup> Given over 30 minutes by syringe pump.
- <sup>m</sup> Run at 94 mL/hr.
- <sup>n</sup> Run at 10 mL/hr.
- <sup>o</sup> Given over one hour by syringe pump.
- <sup>p</sup> Injected via Y-site into an administration set running azithromycin.
- <sup>q</sup> Tested in Ringer's injection, lactated.
- <sup>r</sup> Final concentration after mixing.
- <sup>s</sup> Tested in either dextrose 5% or in sodium chloride 0.9%, but the report did not specify which solution.
- <sup>t</sup> Tested in a 1:1 mixture of (1) dextrose 5% and dextrose 5% in sodium chloride 0.45% with and without potassium chloride 20 mEq/L and also in (2) dextrose 10% in sodium chloride 0.45% with and without potassium chloride 20 mEq/L.
- <sup>u</sup> Tested in a 1:1 mixture of dextrose 5% and TPN #274 (see Appendix).
- <sup>v</sup> Tested in dextrose 5% in sodium chloride 0.45%.
- <sup>w</sup> Test performed using the formulation WITHOUT edetate disodium.
- <sup>x</sup> Test performed using the formulation WITH edetate disodium.
- <sup>y</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.
- <sup>z</sup> Tested as the premixed infusion solution.
- <sup>aa</sup> Salt not specified.
- <sup>bb</sup> Quinupristin and dalfopristin components combined.
- <sup>cc</sup> Test performed using the Cubicin formulation.
- <sup>dd</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.
- <sup>ee</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.
- <sup>ff</sup> Ceftazidime component. Ceftazidime in a 4:1 fixed-ratio concentration with avibactam.
- <sup>gg</sup> Tested in dextrose 5%, sodium chloride 0.9%, and Ringer's injection, lactated.
- <sup>hh</sup> Run at 25 mL/hr with dextrose 5% run at 83 mL/hr.
- <sup>ii</sup> Run at 100 mL/hr.

## Additional Compatibility Information

### Peritoneal Dialysis Solutions

The activity of gentamicin 10 mg/L was evaluated in peritoneal dialysis fluids containing 1.5 or 4.25% dextrose (Dianeal 137, Travenol). Storage at 25°C resulted in no loss of antimicrobial activity in 24 hours.<sup>515</sup>

Gentamicin sulfate (Schering) 3 and 10 mg/L in peritoneal dialysis concentrate with 50% dextrose retained about 90% of

initial activity in 7 hours and about 50 to 70% in 24 hours at room temperature.<sup>1044</sup>

The stability of gentamicin sulfate 8 mg/L, alone and with cefazolin sodium 75 and 150 mg/L, was evaluated in a peritoneal dialysis solution of dextrose 1.5% with heparin sodium 1000 units/L. Gentamicin activity was retained for 48 hours at both 4 and 26°C, alone and with both concentrations of cefazolin. Cefazolin activity was also retained over the study period. At 37°C, gentamicin losses ranged from 4 to 8% and cefazolin losses ranged from 10 to 12% in 48 hours.<sup>1029</sup>

In another study, the stability of gentamicin sulfate (Schering) was evaluated in peritoneal dialysate concentrates containing dextrose 30 and 50% (Dianeal) as well as in a diluted solution containing dextrose 2.5%. The gentamicin sulfate concentrations were 100 and 160 mg/L in the peritoneal dialysate concentrates and 5 and 8 mg/L in the diluted solutions. Gentamicin sulfate was found to be stable in all of these solutions for at least 24 hours at 23°C.<sup>1229</sup>

Gentamicin 4 mcg/mL was evaluated in Dianeal PDS with dextrose 1.5 and 4.25% (Travenol) with cefazolin 125 mcg/mL, heparin 500 units, and albumin human 80 mg in 2-L bags. The gentamicin content was retained for 72 hours.<sup>1413</sup>

The retention of antimicrobial activity of gentamicin sulfate (SoloPak) 120 mg/L alone and with vancomycin hydrochloride (Lilly) 1 g/L was evaluated in Dianeal PD-2 (Travenol) with dextrose 1.5%. Little or no loss of either antibiotic occurred in 8 hours at 37°C. Gentamicin sulfate alone retained activity for at least 48 hours at 4 and 25°C. In combination with vancomycin hydrochloride, antimicrobial activity of both antibiotics was retained for up to 48 hours. However, the authors recommended refrigeration at 4°C for storage periods greater than 24 hours.<sup>1414</sup>

Gentamicin sulfate (Schering) 25 mcg/mL combined separately with the cephalosporins cefazolin sodium (Lilly) and cefoxitin (MSD) at a concentration of 125 mcg/mL in peritoneal dialysis solution (Dianeal 1.5%) exhibited enhanced rates of lethality to *Staphylococcus aureus*, *Escherichia coli*, and *Pseudomonas aeruginosa* compared to any of the drugs alone.<sup>1623</sup>

Gentamicin sulfate (American Pharmaceutical Partners) 8 mcg/mL in Delflex peritoneal dialysis solution bags with 2.5% dextrose (Fresenius) is stable with little or no loss occurring in 14 days refrigerated and at room temperature.<sup>2573</sup>

Gentamicin sulfate (American Pharmaceutical Partners) 8 mcg/mL with vancomycin hydrochloride (Lederle) 25 mcg/mL in Delflex peritoneal dialysis solution bags with 2.5% dextrose (Fresenius) is stable with little or no loss of either drug occurring in 14 days refrigerated and at room temperature.<sup>2573</sup>

Gentamicin sulfate (Pfizer) 20 mg/L in Extraneal with icodextrin 7.5% (Baxter) peritoneal dialysis solution bags exhibited less than 10% loss in 14 days at 37, 25, and 4°C.<sup>3537</sup> Gentamicin sulfate (Pfizer) 20 mg/L with vancomycin hydrochloride (Hospira) 1 g/L in Extraneal with icodextrin 7.5% (Baxter) peritoneal dialysis solution bags exhibited less than 10% loss of either drug in 14 days at 25 and 4°C and 3% loss of gentamicin and 7% loss of vancomycin in 4 days at 37°C.<sup>3537</sup> Gentamicin sulfate (Pfizer) 20 mg/L and cefazolin sodium (Hospira) 500 mg/L in Extraneal with icodextrin 7.5% (Baxter) peritoneal dialysis solution bags exhibited less than 10% loss of either drug in 14 days at 4°C, no loss of gentamicin and 7% loss of cefazolin in 4 days at 25°C, and 1% loss of gentamicin and 5% loss of cefazolin in 1 day at 37°C.<sup>3537</sup>

### ***β*-Lactam Antibiotics**

In common with other aminoglycoside antibiotics, gentamicin activity may be impaired by  $\beta$ -lactam antibiotics. The inactivation is dependent on concentration, temperature, and time of exposure.<sup>68 219 504 574 575 654 667 740 792 816 824 973 1052 1382</sup>

The clinical significance of these interactions in patients appears to be primarily confined to those with renal failure.<sup>218</sup>  
334 361 364 616 737 816 847 Literature reports of greatly reduced aminoglycoside levels in such patients have appeared frequently.<sup>363</sup>  
365 366 367 614 666 962 In addition, the interaction may be clinically important if assays for aminoglycoside levels in serum are sufficiently delayed.<sup>576 618 735 832 847 1052 1382</sup>

Most authors believe that in vitro mixing of penicillins with aminoglycoside antibiotics should be avoided but that clinical use of the drugs in combination can be of great value. It is generally recommended that the drugs be given separately in such combined therapy.<sup>157 218 222 224 361 364 368 369 370</sup>

### **Local Anesthetics**

Gentamicin sulfate 80 mg (2 mL) was physically compatible with 1 mL of each of the following local anesthetics and did not show significant loss in 24 hours at room temperature or under refrigeration.<sup>227</sup>

Lidocaine hydrochloride 1 and 2% (Astra)

Lidocaine hydrochloride 1 and 2% with epinephrine 1:100,000 (Astra)

Mepivacaine hydrochloride 1 and 2% (Winthrop)

### **Heparin**

Addition of gentamicin sulfate (Roussel) 80 mg to the tubing of an infusion solution of sodium chloride 0.9% containing heparin resulted in immediate precipitation.<sup>528</sup>

Gentamicin sulfate 10 mg/L with heparin sodium 1000 units/L in Dianeal with dextrose 5% peritoneal dialysis solution was reported to be conditionally compatible. No significant reduction in gentamicin sulfate concentration occurred in 4 to 6 hours.<sup>228</sup> However, a marked reduction in the anticoagulant activity of heparin sodium occurred if opalescence or a precipitate formed (which results if the undiluted drugs are combined), even if the precipitate redissolved. Heparin activity was retained if one drug was added to a dilute solution of the other and no precipitate formed.<sup>295</sup>

The incompatibility of heparin sodium with gentamicin sulfate is said to result from coprecipitation.<sup>230</sup>

A white precipitate may result from the administration of gentamicin sulfate through a heparinized intravenous cannula.<sup>976</sup> Flushing heparin locks with sodium chloride 0.9% before and after administering drugs incompatible with heparin has been recommended.<sup>4</sup>

### **Sodium Citrate**

The physical stability of gentamicin sulfate (Schering) 1, 2, and 5 mg/mL in sodium citrate 4% anticoagulant solution (Baxter) was evaluated. The combination has been used in preventing hemodialysis catheter-related infections. The gentamicin dilutions were packaged in 3-mL syringes and were stored at 4 and 23°C. The solutions remained clear and colorless for 35 days at both temperatures. The pH was found to be near 5.1 initially and did not change throughout the study. Although the gentamicin content was not measured, the authors pointed out that other studies had reported that the

drug in solutions within the pH range of 4 to 7 was stable for up to 90 days. Furthermore, in another study, sodium citrate also had been documented to be stable for 28 days at room temperature.<sup>2631</sup>

Gentamicin sulfate (Sandoz) 2.5 mg/mL in sodium citrate 4% (Cytasol) was found to be physically and chemically stable for 112 days at 24°C packaged in polyethylene plastic syringes sealed with tip caps.<sup>2824</sup>

# Glycopyrrolate

AHFS 12:08.08

## Products

Glycopyrrolate is available in 1- and 2-mL single-dose vials and 5- and 20-mL multiple-dose vials. Each mL contains glycopyrrolate 0.2 mg, sodium hydroxide and/or hydrochloric acid to adjust the pH, and benzyl alcohol 0.9% in water for injection.<sup>1(8/06)</sup>

### pH

From 2 to 3.<sup>1(8/06)</sup>

### Trade Name(s)

Robinul

## Administration

Glycopyrrolate may be administered by intravenous or intramuscular injection without dilution. The drug may also be given via the tubing of a running intravenous infusion.<sup>1(8/06)</sup> 4

## Stability

Glycopyrrolate is a clear, colorless solution; intact vials should be stored at controlled room temperature.<sup>1(8/06)</sup>

### pH Effects

The stability of glycopyrrolate in solution is pH dependent. At pH 2 to 3, the drug is very stable. Above pH 6, the stability becomes questionable because of ester hydrolysis. The speed of this hydrolysis is increased with increasing pH. A significant decline in glycopyrrolate stability as the pH is increased above 6 can be seen in Table 1.<sup>331</sup>

**Table 1. Stability of glycopyrrolate 0.8 mg/L in dextrose 5% adjusted to various pH values (25°C)**

Admixture pH	Approximate Time for 5% Decomposition (hr)
4	>48
5	>48

Admixture pH	Approximate Time for 5% Decomposition (hr)
6	30
6.5	7
7	4
8	2

Glycopyrrolate 0.8 mg/L in Ringer's injection, lactated, is physically compatible for 48 hours at 25°C. The pH of the solution (6.1) is slightly higher than the pH range yielding acceptable glycopyrrolate stability (2 to 6). However, the drug can be administered via the tubing of a running intravenous infusion of Ringer's injection, lactated.<sup>1(8/06)</sup> 4

Because of the low pH of glycopyrrolate, mixtures with alkaline drugs such as barbiturates result in precipitation of the free acid. If the pH of the admixture is increased above 6 by an alkaline additive or solution, rapid ester hydrolysis of the glycopyrrolate results.<sup>331</sup>

### Syringes

Glycopyrrolate (American Regent) 0.1 mg/mL in sodium chloride 0.9% in polypropylene syringes (Sherwood) was physically stable and exhibited little loss in 24 hours stored at 4 and 23°C.<sup>2199</sup>

Glycopyrrolate (Robins) 0.2 mg/mL packaged as 4 mL of undiluted injection in 6-mL polypropylene syringes (Becton Dickinson) was stored at 4 and 25°C exposed to fluorescent light. The injection remained visually clear, and little loss of glycopyrrolate occurred in 90 days at both storage conditions.<sup>2439</sup>

## Granisetron Hydrochloride

AHFS 56:22.20

### Products

Granisetron hydrochloride is available in 1-mL single-use and 4-mL multiple-use vials containing in each mL the equivalent of granisetron 1 mg and sodium chloride 9 mg.<sup>3123 3124 3125 3126</sup> Preservatives and other excipients can vary among products and may include benzyl alcohol,<sup>3125</sup> methyl- and propylparaben,<sup>3123 3126</sup> and phenol.<sup>3124</sup> Sodium hydroxide and/or hydrochloric acid may have been added to adjust the pH.<sup>3123 3125 3126</sup> Specific product labeling should be consulted for additional formulation details.

Preservative-free formulations of the 1-mg/mL concentration in 1-mL single-use vial also are available.<sup>3124</sup>

Granisetron hydrochloride also is available in 1-mL single-use vials containing the equivalent of granisetron 0.1 mg and sodium chloride 9 mg.<sup>3123 3124 3125</sup> Excipients can vary among products.<sup>3123 3124 3125 3126</sup> Sodium hydroxide and/or hydrochloric acid may have been added to adjust the pH.<sup>3123 3125 3126</sup> Specific product labeling should be consulted for additional formulation details.

### pH

From 4 to 6<sup>3123 3124 3125</sup> or from 4.4 to 5.<sup>3126</sup>

### Equivalency

Granisetron hydrochloride 1.12 mg provides 1 mg of granisetron.<sup>3123 3124 3125 3126</sup>

### Administration

Granisetron hydrochloride may be administered intravenously undiluted over 30 seconds or by intravenous infusion over 5 minutes after dilution with sodium chloride 0.9% or dextrose 5%.<sup>3123 3124 3125 3126</sup>

### Stability

Granisetron hydrochloride is a clear, colorless injection.<sup>3123 3124 3125 3126</sup> Intact vials should be stored at controlled room tempera-

ture and retained in the original carton to protect from light; vials should not be frozen.<sup>3123 3124 3125 3126</sup> The unused portion from a single-use vial should be discarded;<sup>3123</sup> the contents of multiple-use vials should be used within 30 days after initial stopper penetration.<sup>3123 3124 3125 3126</sup> Solutions diluted for infusion in sodium chloride 0.9% or dextrose 5% should be prepared at the time of administration, but have been noted to be stable for at least 24 hours when stored at room temperature under normal lighting conditions.<sup>3123 3124 3125 3126</sup> Solutions should be visually inspected for particulate matter and discoloration prior to administration.<sup>3123 3124 3125 3126</sup>

### Syringes

Granisetron hydrochloride (SmithKline Beecham) 0.05, 0.07, and 0.1 mg/mL (as granisetron) in sodium chloride 0.9% and in dextrose 5% was repackaged in polypropylene syringes (Sherwood Medical) (closure unspecified). Little or no granisetron hydrochloride loss occurred after 14 days at 5 and 24°C.<sup>1968</sup>

Granisetron hydrochloride (SmithKline Beecham) 1 mg/mL was repackaged into Plastipak (Becton Dickinson) polypropylene syringes and stored at room temperature exposed to or protected from light and refrigerated at 4°C. Little granisetron hydrochloride loss occurred in 15 days under any of these storage conditions.<sup>2149</sup>

### Central Venous Catheter

Granisetron hydrochloride (SmithKline Beecham) 10 mcg/mL in dextrose 5% was found to be compatible with the ARROW-g+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

Test Drug	Mfr	Conc/L or %	Mfr	Conc/L or %	Test Solution	Remarks	Ref	C/I
Butorphanol tartrate	HE	80 mg	NIN	30 and 60 mg	NS <sup>e</sup>	Physically compatible with little to no loss of either drug in 14 days at 4°C protected from light or 48 hr at 25°C in room light	3120	C
Butorphanol tartrate	HE	80 mg	NIN	30 and 60 mg	NS <sup>f</sup>	Physically compatible with little to no loss of either drug in 14 days at 4°C protected from light or 48 hr at 25°C in room light	3120	C
Dexamethasone sodium phosphate	AMR	92 mg	SKB	10 and 40 mg	D5W, NS <sup>a</sup>	Visually compatible. Little loss of either drug in 14 days at 4 and 24°C in dark	1875	C
Dexamethasone sodium phosphate	AMR	660 mg	SKB	10 and 40 mg	D5W, NS <sup>a</sup>	Visually compatible. Little dexamethasone and 8% granisetron loss in 14 days at 4 and 24°C in dark	1875	C
Dexamethasone sodium phosphate	MSD	75 and 345 mg	BE	55 and 51 mg	D5W, NS <sup>a</sup>	Visually compatible. Little loss of either drug in 72 hr at room temperature	1884	C
Dexamethasone sodium phosphate	<sup>d</sup>	100 mg		26 mg	NS	Physically compatible for 24 hr at 25°C in light	2999	C
Fosaprepitant dimeglumine	MSD	1 g		26 mg	NS	Physically compatible for 24 hr at 25°C in light	2999	C
Fosaprepitant dimeglumine	MSD <sup>b</sup>	1 g		26 mg	NS	Physically compatible for 24 hr at 25°C in light	2999	C
Fosaprepitant dimeglumine	MSD <sup>c</sup>	1 g		26 mg	NS	Physically compatible for 24 hr at 25°C in light	2999	C
Methylprednisolone sodium succinate	DAK	2.26 g	BE	56 mg	D5W, NS <sup>a</sup>	Visually compatible. Little loss of either drug in 72 hr at room temperature	1884	C
Methylprednisolone sodium succinate	<sup>d</sup>	700 mg		26 mg		Physically compatible for 24 hr at 25°C in light	2999	C

<sup>a</sup> Tested in PVC containers.

<sup>b</sup> Tested with dexamethasone sodium phosphate 100 mg/L.

<sup>c</sup> Tested with methylprednisolone sodium succinate 700 mg/L.

<sup>d</sup> Tested with fosaprepitant dimeglumine (MSD) 1 g/L.

<sup>e</sup> Tested in polyolefin containers.

<sup>f</sup> Tested in glass containers.

## Drugs in Syringe Compatibility

### Granisetron HCl

Test Drug	Mfr	Amt	Mfr	Amt	Remarks	Ref	C/I
Dexamethasone sodium phosphate	MSD	0.2 and 1 mg/mL <sup>a</sup>	BE	0.15 mg/mL <sup>a</sup>	Visually compatible. Little loss of either drug in 72 hr at room temperature	1884	C
Methylprednisolone sodium succinate	DAK	6 mg/mL <sup>a</sup>	BE	0.15 mg/mL <sup>a</sup>	Visually compatible. Little loss of either drug in 72 hr at room temperature	1884	C

<sup>a</sup> Diluted with water.

Vinblastine sulfate	LI	0.12 mg/mL <sup>a</sup>	SKB	0.05 mg/mL <sup>a</sup>	Physically compatible for 4 hr at 23°C	2000	C
Vincristine sulfate	LI	0.01 and 0.34 mg/mL <sup>b</sup>	SKB	1 mg/mL	Physically compatible with little or no loss of either drug in 4 hr at 22°C	1883	C
Vinorelbine tartrate	BW	1 mg/mL <sup>a</sup>	SKB	0.05 mg/mL <sup>a</sup>	Physically compatible for 4 hr at 23°C	2000	C
Zidovudine	BW	4 mg/mL <sup>a</sup>	SKB	0.05 mg/mL <sup>a</sup>	Physically compatible for 4 hr at 23°C	2000	C

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Tested in Ringer's injection, lactated.

<sup>d</sup> Tested in bacteriostatic sodium chloride 0.9% preserved with benzyl alcohol 0.9%.

<sup>e</sup> Granisetron HCl tested in both sodium chloride 0.9% and dextrose 5%.

<sup>f</sup> Lyophilized formulation tested.

<sup>g</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>h</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>i</sup> Ampicillin component. Ampicillin in a 2:1 fixed-ratio concentration with sulbactam.

<sup>j</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>k</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>l</sup> Not specified whether concentration refers to single component or combined components.

<sup>m</sup> Test performed using the formulation WITH edetate disodium.

## Haloperidol Lactate

AHFS 28:16.08.08

### Products

Haloperidol lactate is available in 1-mL ampuls and vials and 10-mL multiple-dose vials. Each mL of solution contains haloperidol 5 mg (as the lactate) and lactic acid for pH adjustment.<sup>1(2/08)</sup>

### pH

From 3 to 3.6<sup>1(2/08)</sup> or 3.8.<sup>17</sup>

### Trade Name(s)

Haldol

### Administration

Haloperidol lactate should be administered intramuscularly,<sup>1(2/08)</sup> 4 although intravenous administration has been performed.<sup>4 571 1258</sup>

### Stability

Haloperidol lactate should be stored at controlled room temperature and protected from light; freezing and temperatures above 40°C should be avoided.<sup>1(2/08)</sup> 4

### Central Venous Catheter

Haloperidol lactate (McNeil) 0.2 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

TPN #189 <sup>g</sup>			SE	10 mg/mL	Visually compatible for 24 hr at 22°C	1767	C
TPN #212 to #215 <sup>g</sup>			MN	0.2 mg/mL <sup>a</sup>	Physically compatible for 4 hr at 23°C	2109	C
Vinorelbine tartrate	BW	1 mg/mL <sup>b</sup>	MN	0.2 mg/mL <sup>b</sup>	Physically compatible for 4 hr at 22°C	1558	C

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Tested in bacteriostatic sodium chloride 0.9% preserved with benzyl alcohol 0.9%.

<sup>d</sup> Injected over one minute.

<sup>e</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>f</sup> Tested in Ringer's injection, lactated.

<sup>g</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>h</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>i</sup> Lyophilized formulation tested.

<sup>j</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>k</sup> Quinupristin and dalfopristin components combined.

<sup>l</sup> Run at 1000 units/hr.

<sup>m</sup> Salt not specified.

<sup>n</sup> Test performed using the formulation WITH edetate disodium.

# Heparin Sodium

AHFS 20:12.04.16

## Products

Heparin sodium is available from various manufacturers in concentrations ranging from 1000 to 20,000 units/mL, packaged in sizes ranging from 0.5- to 1-mL ampuls, vials, or prefilled syringes to 30-mL multiple-dose vials. Benzyl alcohol or parabens also may be present as preservatives, and hydrochloric acid and/or sodium hydroxide may have been added to adjust pH. Sodium chloride may have been added to some products for isotonicity. In addition, dilute solutions of 10 and 100 units/mL in 1- to 5-mL disposable syringes and 1- to 30-mL vials are available for use in flushing heparin locks.<sup>4</sup>

Heparin sodium also is available premixed in various concentrations in sodium chloride 0.45 and 0.9% and dextrose 5%.<sup>4</sup>

## pH

Heparin sodium injection and heparin lock flush solution are adjusted to pH 5 to 7.5 during manufacturing.<sup>1(3/09) 17</sup>

## Osmolality

The osmolality of heparin sodium (Elkins-Sinn) 1000 units/mL was determined to be 384 mOsm/kg by freezing-point depression and 283 mOsm/kg by vapor pressure.<sup>1071</sup>

Commercially available heparin sodium infusion solutions in sodium chloride 0.9% and dextrose 5% have osmolalities of 322 and 270 mOsm/kg, respectively.<sup>4</sup>

## Osmolarity

One heparin lock flush solution is reported to have an osmolarity of 392 mOsm/L.<sup>4</sup>

## Administration

Heparin sodium may be administered by deep subcutaneous injection, by intermittent intravenous injection either undiluted or diluted in 50 to 100 mL of dextrose 5% or sodium chloride 0.9%, or by continuous intravenous infusion in a liter of compatible solution, preferably using an electronic rate-control device. The container should be inverted at least 6 times after heparin sodium addition to prevent pooling of the heparin. Intramuscular injection should not be used because of pain and hematoma formation.<sup>4</sup>

Care is required when adding heparin sodium to infusion solutions, especially in flexible containers. When heparin sodium was added to a flexible polyvinyl chloride (PVC) container of sodium chloride 0.9% hanging in the use position, pooling of the heparin resulted; 97% of the heparin was delivered in the first 30% of the solution. Repeated inversion and agitation of the containers to effect thorough mixing eliminates this pooling (and the danger of overdosage), yielding an even distribution and a constant delivery concentration.<sup>85</sup>

## Stability

Heparin sodium solutions are colorless to slightly yellow.<sup>4</sup> Heparin sodium solution should not be used if it is discolored or contains a precipitate. Heparin sodium should be stored at controlled room temperature<sup>1(3/09) 4</sup> and protected from freezing and temperatures exceeding 40°C.<sup>4 21</sup> In a study of hospital-manufactured heparin sodium 1 unit/mL in sodium chloride 0.9%, full anticoagulant activity was retained for at least 12 months after sterilization by autoclaving and subsequent storage at room temperature exposed to daylight.<sup>675</sup>

## pH Effects

A pH profile of heparin sodium 20,000 units/L in dextrose 5% over a pH range of 3.8 to 7.6 did not reveal a loss during the 24-hour study.<sup>21</sup> In another report, heparin sodium in sodium chloride 0.9% was tested at pH 3.2 (adjusted with hydrochloric acid) and 9.2 (adjusted with sodium hydroxide). No loss was noted in 24 hours.<sup>57</sup> However, a pH profile of heparin sodium 660 units/mL, when autoclaved for 10 minutes at 10 pounds/inch<sup>2</sup> at 115°C, showed loss of activity at pH values above 8.5 and especially below 5.<sup>243</sup>

## Syringes

The stability of 50 mL of a 500-unit/mL heparin sodium solution in sodium chloride 0.9% packaged in 50-mL polypropylene syringes was studied. Storage both at room temperature and at 0 to 4°C showed an overall trend to lower activity by about 8% after 3 weeks.

When glass containers were compared to plastic syringes, the glass containers consistently showed lower retained activity in as little as 2 hours after preparation. The possibility of adsorption to glass surfaces was noted<sup>676</sup> but has not been demonstrated.

Heparin sodium 1 unit/mL, prefilled into Injekt (Braun) all-plastic syringes having polyethylene barrels and polypropylene plungers, showed no significant activity loss over 52 weeks at 37°C due to decomposition or sorption. However, plastic syringes with rubber-tipped plungers, such as Plastipak (Becton Dickinson) and Perfusor (Braun), exhibited extra ultraviolet peaks, presumably due to leaching of rubber components.<sup>1491</sup>

Heparin sodium (Leo) 300 units/mL in dextrose 5% or water for injection was drawn into 50-mL polypropylene syringes (Plastipak, Becton Dickinson) and stored for 8 hours at room temperature and 4°C. No loss in either solvent occurred.<sup>1799</sup>

The stability of heparin sodium repackaged in 10-mL polypropylene syringes for use in CADD-Micro syringe pumps was evaluated. 10 mL of heparin sodium 1000 units/mL (Elkins-Sinn) and 40,000 units/mL (Schein) were packaged in the test syringes

and capped. Syringes were stored at a near-body temperature of 30°C for 30 days. Little or no loss of heparin sodium content occurred; actual activity in prolonging blood clotting was not evaluated.<sup>2275</sup>

### Sorption

Heparin sodium, BP, 2000 units/2 mL was stored for 18 hours at room temperature in plastic syringes: Brunswick (Sherwood Medical), Plastipak (Becton Dickinson), Steriseal (Needle Industries), and Sabre (Gillette U.K.). The first 3 syringes have polypropylene barrels; the Sabre has a combination polypropylene–polystyrene barrel. No significant loss of heparin occurred due to sorption.<sup>784</sup>

Heparin sodium (Leo) 300 units/mL in dextrose 5% or water for injection was delivered at 4 mL/hr by syringe pump through PVC and polyethylene-lined PVC infusion tubing for 12 hours at room temperature. No loss occurred due to sorption to the polyethylene-lined tubing. However, losses of about 15 to 25%

occurred with the PVC tubing and were especially high during the first 15 minutes of infusion.<sup>1799</sup>

### Filtration

Heparin sodium (Abbott) 10,000 units/L in dextrose 5% and sodium chloride 0.9% was filtered at 120 mL/hr for 6 hours through a 0.22- $\mu$ m cellulose ester membrane filter (Ivex-2). No significant loss due to binding to the filter was noted.<sup>533</sup>

### Central Venous Catheter

Heparin sodium (Elkins-Sinn) 100 units/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

<sup>y</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>z</sup> Ceftazidime component. Ceftazidime in a 4:1 fixed-ratio concentration with avibactam.

<sup>aa</sup> Tested in both dextrose 5% and Ringer's injection, lactated.

<sup>bb</sup> Run at 1000 units/hr.

<sup>cc</sup> Test performed using the formulation WITH edetate disodium.

## Additional Compatibility Information

### Parenteral Nutrition Admixtures

In solutions of amino acids 5% and dextrose 5 or 25% with vitamins or trace elements, heparin activity was retained for 24 hours at 25°C. However, the activity fell significantly after 24 hours.<sup>900</sup>

Flocculation of fat emulsion (Kabi-Vitrum) was reported during Y-site administration into a line being used to infuse a parenteral nutrition solution containing both calcium gluconate and heparin sodium. Subsequent evaluation indicated that the combination of calcium gluconate (0.46 and 1.8 mM/125 mL) plus heparin sodium (25 and 100 units/125 mL) in amino acids plus dextrose would induce flocculation of the fat emulsion within 2 to 4 minutes at concentrations that resulted in no visually apparent flocculation in 30 minutes with either agent alone.<sup>1214</sup>

Calcium chloride concentrations of 1 to 20 mM normally result in slow flocculation of fat emulsion 20%, intravenous, over a period of hours. When heparin sodium 5 units/mL was added, the flocculation rate accelerated greatly; a cream layer was observed visually in a few minutes. This effect was not observed when sodium ion was substituted for the divalent calcium.<sup>1406</sup>

Destabilization of fat emulsion (Intralipid 20%) was observed when administered simultaneously with a parenteral nutrition admixture. The damage, detected by viscosity measurement, occurred immediately upon contact at the Y-site. The extent of the destabilization was dependent on the concentration of the heparin and the presence of MVI Pediatric with its surfactant content. In addition to the viscosity changes, phase separation was observed in 2 hours. Parenteral nutrition admixtures containing heparin should never be premixed with fat emulsion as a 3-in-1 total nutrient admixture because of this emulsion destabilization. The damage might be minimized during Y-site co-administration as long as the heparin was kept at a sufficiently low concentration (no visible separation occurred at a heparin concentration of 0.5 unit/mL) and the length of tubing between the Y-site and the patient was minimized.<sup>2282</sup>

However, because the damage to emulsion integrity has been found to occur immediately upon mixing with heparin in the presence of the calcium ions in parenteral nutrition admixtures<sup>1214 2215 2282</sup> and no evaluation and documentation of the clinical safety of using such destabilized emulsions has been performed, use of such damaged emulsions in patients is suspect.

### Peritoneal Dialysis Solutions

The activity of heparin 35,000 units/L was evaluated in peritoneal dialysis fluids containing 1.5 and 2.5% dextrose (Dianeal, Travenol). Storage at 25°C resulted in an apparent temporary 50% loss of heparin activity in 4 hours with recovery in 6 hours. Heparin activity was then retained for 14 days at 4°C.<sup>900</sup>

Gentamicin sulfate 10 mg/L with heparin sodium 1000 units/L in Dianeal with dextrose 5% had no significant reduction in gentamicin sulfate concentration or of heparin sodium in 4 to 6 hours.<sup>228</sup> However, a marked reduction in the anticoagulant

activity of heparin sodium occurred if opalescence or a precipitate is formed, which results if the undiluted drugs are combined, even if the precipitate redissolves. Heparin activity was retained if one drug was added to a dilute solution of the other and no precipitate formed.<sup>295</sup>

Vancomycin hydrochloride (Lilly) 15 mg/L to 5.3 g/L in Dianeal with dextrose 2.5 or 4.25% was physically compatible with heparin sodium (Organon) 500 to 14,300 units/L for 24 hours at 25°C under fluorescent light. However, a white precipitate formed immediately in combinations of heparin sodium with vancomycin hydrochloride 6.9 to 14.3 g/L.<sup>1322</sup>

### Heparin Locks

Heparin locks, weak heparin solutions instilled or "locked" into infusion ports or sets through a resealing latex diaphragm, are useful in providing an established intravenous route for intermittent intravenous injections. To maintain patency, a weak heparin solution is left in the tubing. Concentrations of heparin sodium used have varied from about 10 to 1000 units/mL of sodium chloride 0.9%, with 10 and 100 units/mL being the most common. The volume of dilute heparin sodium in sodium chloride 0.9% usually used to flush the set is 0.2 to 1 mL.<sup>255 256 257 258 405 677 678 901 2119</sup> However, the use of sodium chloride 0.9% instead of a solution containing heparin has been suggested to maintain patency. Studies have found sodium chloride 0.9% to be as effective in maintaining patency as 10- and 100-unit/mL solutions of heparin.<sup>902 903 1109 1266 1267 1268 1269 1639 1640 1641 1656 1839 1959 2003 2119</sup> Other investigators reported that even small amounts of heparin solution are more effective than sodium chloride 0.9% alone.<sup>678 1270 2120 2121</sup>

Evaluations of the use of heparinized solutions as locks or continuous flow solutions to help maintain patency in central venous catheters and arterial catheters have resulted in similarly variable results and recommendations.<sup>2122 2123 2124 2125 2126</sup> Although use of such heparinized solutions has been generally considered a benign technique causing minimal problems, a number of adverse effects have been reported, especially from solutions with a high heparin concentration and/or numerous heparin flushes.<sup>2127 2128 2129 2130 2131 2132</sup>

Vancomycin hydrochloride (Lilly) 25 mcg/mL and heparin sodium (Elkins-Sinn) 100 units/mL in 0.9% sodium chloride injection as a catheter flush solution was evaluated for stability when stored at 4°C for 14 days. The flush solution was visually clear, and vancomycin activity and heparin activity were retained throughout the storage period. However, an additional 24 hours at 37°C to simulate use conditions resulted in losses of both agents ranging from 20 to 37%.<sup>1933</sup>

Vancomycin hydrochloride 25 mcg/mL combined with heparin sodium (Hospira) 10 units/mL in sterile water for injection for use as a lock solution was found to be physically compatible. Little or no vancomycin loss occurred in 3 days at 4°C. However, losses of 8% occurred in 3 days at 27°C and 1 day at 40°C.<sup>2820</sup>

If ciprofloxacin (Sicor) 2 mg/mL was added to this flush solution, a white precipitate appeared within 1 day. Losses of both ciprofloxacin and vancomycin occurred as well.<sup>2820</sup>

A combination of daptomycin (Cubist) 5 mg/mL and heparin sodium (Hospira) 100 units/mL in Ringer's injection, lactated was evaluated for stability as a lock solution stored in 5-mL aliquots in 5-mL polypropylene syringes (Becton Dickinson) at 4 and –20°C.<sup>2978</sup> The solution remained clear and colorless on visual inspection and little or no loss of either drug occurred throughout the 14-day study period.<sup>2978</sup>

### ***Methylprednisolone***

The compatibility of methylprednisolone sodium succinate (Upjohn) with heparin sodium added to an auxiliary medication infusion unit has been studied. Primary admixtures were prepared by adding heparin sodium 10,000 units/L to dextrose 5%, dextrose 5% in sodium chloride 0.9%, and Ringer's injection, lactated. Up to 100 mL of the primary admixture was added along with methylprednisolone sodium succinate (Upjohn) to the auxiliary medication infusion unit with the following results:<sup>329</sup>

Methylprednisolone Sodium Succinate	Heparin Sodium 10,000 units/L of Primary Solution	Results
500 mg	D5S, D5W qs 100 mL	Clear solution for 24 hr
500 mg	LR qs 100 mL or added to 100 mL LR	Clear solution for 6 hr
1000 mg	D5S, D5W qs 100 mL	Clear solution for 6 hr
1000 mg	Added to 100 mL D5W	Clear solution for 24 hr
1000 mg	LR qs 100 mL or added to 100 mL LR	Clear solution for 4 to 6 hr
2000 mg	D5W qs 100 mL	Clear solution for 6 hr
2000 mg	D5S, LR qs 100 mL	Clear solution for 24 hr

# Hetastarch in Lactated Electrolyte

## AHFS 40:12

### Products

Hetastarch 6% in lactated electrolyte is available in 500-mL flexible plastic infusion containers.<sup>2867</sup> Each 100 mL of solution contains hetastarch 6 g, sodium chloride 672 mg, sodium lactate anhydrous 317 mg, dextrose hydrous 99 mg, calcium chloride dihydrate 37 mg, potassium chloride 22 mg, and magnesium chloride hexahydrate 9 mg in water for injection.<sup>2867</sup> The concentrations of electrolytes are shown in Table 1.<sup>2867</sup>

**Table 1. Electrolyte composition**<sup>2867</sup>

Electrolyte	mEq/L
Sodium	143
Calcium	5
Potassium	3
Magnesium	0.9
Chloride	124
Lactate	28

### pH

Approximately 5.9 with negligible buffering capacity.<sup>2867</sup>

### Osmolarity

The calculated osmolarity is approximately 307 mOsm/L.<sup>2867</sup>

### Tonicity

The injection is an isotonic solution.<sup>2867</sup>

### Trade Name(s)

Hextend

### Administration

Hetastarch 6% in lactated electrolyte is administered only by intravenous infusion.<sup>2867</sup> The dosage and rate of infusion should be individualized according to the patient's condition and response.<sup>2867</sup> The container is made of polyvinyl chloride (PVC) and is latex free.<sup>2867</sup> The product should be inspected for discoloration and particulate matter prior to use.<sup>2867</sup> If the drug is administered by pressure infusion, all air should be withdrawn or expelled from the container through the medication port prior to infusion.<sup>2867</sup>

Solutions such as this product that contain calcium should not be administered simultaneously with blood through the same set because of the likelihood of coagulation.<sup>2867</sup>

### Stability

Intact containers of hetastarch 6% in lactated electrolyte should be stored at 25°C and protected from freezing and excessive heat.<sup>2867</sup> Brief exposure at temperatures up to 40°C does not adversely affect the product.<sup>2867</sup>

Hetastarch 6% in lactated electrolyte is a clear, pale yellow to amber solution.<sup>2867</sup> Prolonged exposure to adverse conditions may result in the formation of a turbid deep brown appearance or crystalline precipitate; such solutions should not be used.<sup>2867</sup>

## Hetastarch in Sodium Chloride 0.9%

### AHFS 40:12

#### Products

Hetastarch is available as a 6% (6 g/100 mL) injection in sodium chloride 0.9% in 500-mL plastic containers.<sup>3050</sup> The solution also contains sodium hydroxide for pH adjustment during manufacturing.<sup>3050</sup>

#### pH

Approximately 5.9.<sup>3050</sup>

#### Osmolarity

The product has a calculated osmolarity of 309 mOsm/L.<sup>3050</sup>

#### Sodium Content

Hetastarch 6% in sodium chloride 0.9% provides 77 mEq of sodium per 500-mL container.<sup>3050</sup>

#### Trade Name(s)

Hespan

#### Administration

Hetastarch is administered only by intravenous infusion.<sup>3050</sup> The dosage and rate of infusion must be individualized to the patient's condition and response.<sup>3050</sup>

#### Stability

Hetastarch injection is a clear, pale yellow to amber colloidal solution.<sup>3050</sup> The product should be stored at controlled room temperature and protected from freezing and excessive heat.<sup>3050</sup> Brief exposure to temperatures up to 40°C does not affect stability; however, prolonged storage under adverse conditions may result in the formation of a crystalline precipitate or a change to a deep brown turbid appearance.<sup>3050</sup> Such solutions should not be administered.<sup>3050</sup>

Containers are for single use; any unused portions should be discarded.<sup>3050</sup>

Hetastarch is derived from a waxy starch composed almost entirely of amylopectin.<sup>3050</sup> Amylose has been shown to associate and precipitate over time in solution.<sup>2296</sup> Before hetastarch is used, the colloidal solution should be checked for clarity and particulates and the flexible plastic containers should be squeezed to check for small leaks.<sup>3050</sup>

## Compatibility Information

# Hyaluronidase

AHFS 44:00

## Products

Hyaluronidase is supplied as a 150-unit/mL solution in 1-mL fill vials. Each mL also contains sodium chloride 8.5 mg, edetate disodium 1 mg, calcium chloride 0.4 mg, and thimerosal not more than 0.1 mg in sodium phosphate buffer.<sup>1(11/05)</sup>

### pH

From 6.4 to 7.4.<sup>4</sup>

### Osmolality

From 295 to 355 mOsm/kg.<sup>1(11/05)</sup>

### Trade Name(s)

Amphadase

## Administration

Hyaluronidase is administered subcutaneously, intradermally, or intramuscularly along with other drugs or solutions. The solutions should be isotonic for subcutaneous administration. It should not be administered intravenously.<sup>1(11/05) 4</sup>

## Stability

Hyaluronidase injection in intact vials should be stored under refrigeration at 2 to 8°C. It should not be used if it is discolored or contains a precipitate.<sup>4</sup>

Hyaluronidase (Wyeth) 75 units/mL in citric acid/sodium citrate buffer (pH 4.5) was found to lose about 7 to 8% activity in 24 hours at 4 and 23°C. Hyaluronidase activity decreased by 25 to 33% in 48 hours.<sup>1907</sup>

## Hydralazine Hydrochloride

AHFS 24:08.20

### Products

Hydralazine hydrochloride is available in 1-mL vials. Each mL of solution contains hydralazine hydrochloride 20 mg, methylparaben 0.65 mg, propylparaben 0.35 mg, and propylene glycol 103.6 mg in water for injection. The pH may have been adjusted with hydrochloric acid and/or sodium hydroxide.<sup>1(1/09)</sup>

### pH

From 3.4 to 4.4.<sup>1(1/09)</sup>

### Administration

Hydralazine hydrochloride may be administered intramuscularly or as a rapid direct intravenous injection; the manufacturer does not recommend adding the drug to infusion solutions.<sup>1(1/09)</sup> 4

### Stability

Hydralazine hydrochloride in intact vials should be stored at controlled room temperature and protected from freezing.<sup>1(1/09)</sup> 4 Refrigeration of the intact containers may result in precipitation or crystallization.<sup>593</sup>

Hydralazine hydrochloride undergoes color changes in most infusion solutions. However, it has been stated that color changes within 8 to 12 hours of admixture preparation in solutions stored at 30°C are not indicative of drug losses.<sup>4</sup> The manufacturer does not recommend admixture in infusion solutions.<sup>1(1/09)</sup>

Hydralazine hydrochloride may react with various metals<sup>1(1/09)</sup> to yield discolored solutions, often yellow or pink. One report indicated a pink discoloration in prefilled syringes when the

hydralazine hydrochloride had been drawn up through filter needles (Monoject) with a stainless steel filter and stored for up to 12 hours. The reaction is not specific to any one metal. Consequently, contact with metal parts should be minimized, and hydralazine hydrochloride should be prepared just prior to use.<sup>906</sup>

### pH Effects

Hydralazine hydrochloride exhibits maximum stability at pH 3.5 and is stable over the pH range of 3 to 5. It undergoes more rapid decomposition as the pH becomes alkaline.<sup>106</sup> 466

### Light Effects

Exposure to light increases the rate of hydralazine hydrochloride decomposition during long-term storage. At a concentration of 0.35 mg/mL in sodium chloride 0.9% in glass bottles, 10% decomposition was calculated to occur in 14.4 weeks in the dark and 12.3 weeks under fluorescent light. In PVC containers, decomposition occurs more rapidly; a 10% loss was calculated to occur in 12.8 weeks in the dark and 9.9 weeks under fluorescent light.<sup>1561</sup>

### Sorption

Hydralazine hydrochloride 27 mg/L in sodium chloride 0.9% in PVC bags exhibited approximately 10% loss in 1 week at 15 to 20°C due to sorption.<sup>536</sup> However, no loss due to sorption occurred during a 7-hour simulated infusion through an infusion set consisting of a cellulose propionate burette chamber and 170 cm of PVC tubing.<sup>606</sup>

Hydralazine hydrochloride was shown not to exhibit sorption to polyethylene tubing, Silastic tubing, and polypropylene syringes.<sup>606</sup>

# Hydrocortisone Sodium Succinate

AHFS 68:04

## Products

Hydrocortisone sodium succinate is available in a variety of sizes and containers,<sup>4</sup> including 100-mg conventional vials containing hydrocortisone sodium succinate equivalent to hydrocortisone 100 mg with monobasic sodium phosphate anhydrous 0.8 mg and dibasic sodium phosphate dried 8.73 mg. Reconstitute the vial by adding not more than 2 mL of bacteriostatic water for injection or bacteriostatic sodium chloride injection.<sup>1(5/08)</sup>

Hydrocortisone sodium succinate is also supplied in "Act-O-Vial" containers of 100, 250, 500, and 1000 mg. For the "Act-O-Vial" containers, press the plastic activator down to force the diluent into the lower chamber. Agitate gently to dissolve the drug. When reconstituted, each mL of solution contains:<sup>1(5/08)</sup>

Component	100 mg	250, 500, 1000 mg
Hydrocortisone equivalent (as sodium succinate)	50 mg	125 mg
Monobasic sodium phosphate anhydrous	0.4 mg	1 mg
Dibasic sodium phosphate dried	4.38 mg	11 mg
Benzyl alcohol	~9 mg	~8.3 mg
Water for injection	qs	qs

The pH has been adjusted when necessary with sodium hydroxide.

## pH

From 7 to 8.<sup>1(5/08) 4</sup>

## Osmolality

The osmolality of hydrocortisone sodium succinate (Abbott) 50 mg/mL was determined to be 292 mOsm/kg by freezing-point depression and 260 mOsm/kg by vapor pressure.<sup>1071</sup>

## Sodium Content

Hydrocortisone sodium succinate contains 2.066 mEq of sodium per gram of drug.<sup>846</sup>

## Trade Name(s)

Solu-Cortef

## Administration

Hydrocortisone sodium succinate may be administered by intramuscular injection, direct intravenous injection over 30 seconds to several minutes, or continuous or intermittent intravenous infusion at a concentration of 0.1 to 1 mg/mL in a compatible infusion solution. Benzyl alcohol-containing products should not be used in premature infants.<sup>1(5/08) 4</sup>

## Stability

Hydrocortisone sodium succinate in intact containers should be stored at controlled room temperatures of 20 to 25°C.<sup>1(5/08)</sup> After reconstitution, solutions are stable at controlled room temperature or below if protected from light. The solution should only be used if it is clear. Unused solutions should be discarded after 3 days. Hydrocortisone sodium succinate is heat labile and must not be autoclaved.<sup>1(5/08) 4</sup>

## pH Effects

Hydrocortisone sodium succinate is optimally stable at pH 7 to 8. It is stable for 72 hours at pH 6 and for 12 hours at pH 5. More acidic solutions cause precipitation.<sup>41</sup>

Solutions of hydrocortisone buffered to pH 9.1 showed oxidation to 21-dehydrocortisone at rates of 1.6 to 2.8%/hr at 26°C. This rate is 4 or 5 times greater than that observed at pH 6.9 to 7.9.<sup>531</sup>

## Freezing Solutions

Hydrocortisone sodium succinate (Upjohn) 500-mg/4-mL reconstituted solution exhibited no loss over 4 weeks when stored frozen.<sup>69</sup>

## Intrathecal Injections

In a study of solutions for intrathecal injection, hydrocortisone sodium succinate (Upjohn) was reconstituted to a concentration of 1 mg/mL with Elliott's B solution (295 mOsm/kg, pH 7.3), sodium chloride 0.9% (296 mOsm/kg, pH 7), and Ringer's injection, lactated (258 mOsm/kg, pH 7). In Ringer's injection, lactated and sodium chloride 0.9%, no decomposition was observed in 24 hours at room temperature under fluorescent light or at 30°C. However, in 7 days, approximately 10% decomposition occurred at room temperature and about 15% at 30°C. In Elliott's B solution, hydrocortisone sodium succinate is much less stable. In 24 hours, a 7% loss occurred at room temperature and a 12% loss occurred at 30°C, increasing to 21 and 32%, respectively, at 72 hours. Less than 10% decomposition of this combination occurred in 4 to 8 hours.<sup>327</sup>

In another study, the stability and compatibility of cytarabine (Upjohn), methotrexate (NCI), and hydrocortisone (Upjohn), mixed together in intrathecal injections, were evaluated. Two combinations were tested: (1) cytarabine 50 mg, methotrexate 12 mg (as the sodium salt), and hydrocortisone 25 mg (as the sodium succinate salt); and (2) cytarabine 30 mg, methotrexate 12 mg (as the sodium salt), and hydrocortisone 15 mg (as the sodium succinate salt). Each drug combination was added to 12 mL of Elliott's B solution (NCI), sodium chloride 0.9% (Abbott), dextrose 5% (Abbott), and Ringer's injection, lactated (Abbott) and stored for 24 hours at 25°C. Cytarabine and methotrexate were both chemically stable, with no drug loss after the full 24 hours in all solutions. Hydrocortisone also

was stable in the sodium chloride 0.9%, dextrose 5%, and Ringer's injection, lactated, with about a 2% drug loss. However, in Elliott's B solution, hydrocortisone was significantly less stable, with a 6% loss in the 25-mg concentration over 24 hours. The 15-mg concentration was worse, with a 5% loss in 10 hours and a 13% loss in 24 hours. The higher pH of Elliott's B solution and the lower concentration of hydrocortisone may have been factors in this increased decomposition. All mixtures were physically compatible for 24 hours, but a precipitate formed after several days of storage.<sup>819</sup>

Hydrocortisone sodium succinate (Upjohn) 2 mg/mL diluted in Elliott's B solution (Orphan Medical) was packaged as 20 mL in 30-mL glass vials and 20-mL plastic syringes (Becton Dickinson) with Red Cap (Burron) Luer-lok syringe tip caps. The solution was physically compatible and chemically stable exhibiting about 9% or less loss in 24 hours at 23°C and 7% or less loss in 48 hours at 4°C.<sup>1976</sup>

Bacterially contaminated intrathecal solutions could pose grave risks and, consequently, such solutions should be administered as soon as possible after preparation.<sup>328</sup>

### Syringes

Hydrocortisone sodium succinate (Upjohn) 10 mg/mL in sodium chloride 0.9% was packaged in polypropylene syringes (Becton Dickinson) and stored under refrigeration at 5°C and at room temperature of 25°C. The drug solution remained clear throughout the study, and about 2% hydrocortisone loss occurred after 21

days under refrigeration. At room temperature, about 5% loss occurred in 3 days and 10% loss occurred in 7 days. Stability in glass containers was found to be comparable.<sup>2331</sup>

Hydrocortisone sodium succinate (Pharmacia) 50 mg/mL in sterile water for injection packaged in polypropylene syringes (Braun) was visually compatible with calculated shelf lives of 6.8 days at room temperature and 81 days under refrigeration.<sup>2654</sup>

### Sorption

Hydrocortisone sodium succinate was shown not to exhibit sorption to polyvinyl chloride (PVC) bags and tubing, polyethylene tubing, Silastic tubing, and polypropylene syringes.<sup>12 536 606</sup>

### Filtration

Hydrocortisone sodium succinate (Upjohn) 10 mg/L in dextrose 5% and sodium chloride 0.9% did not display significant sorption to a 0.45- $\mu$ m cellulose membrane filter (Abbott S-A-I-F) during an 8-hour simulated infusion.<sup>567</sup>

### Central Venous Catheter

Hydrocortisone sodium succinate (Abbott) 1 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

Vecuronium bromide	OR	0.1 mg/mL <sup>a</sup>	AB	1 mg/mL <sup>a</sup>	Physically compatible for 24 hr at 28°C	1337	C
Vinorelbine tartrate	BW	1 mg/mL <sup>b</sup>	UP	1 mg/mL <sup>b</sup>	Physically compatible for 4 hr at 22°C	1558	C

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Tested in combination with heparin sodium (Riker) 1000 units/L in dextrose 5%, sodium chloride 0.9%, and Ringer's injection, lactated.

<sup>d</sup> Tested in dextrose 5% in Ringer's injection, dextrose 5% in Ringer's injection, lactated, dextrose 5%, Ringer's injection, lactated, and sodium chloride 0.9%.

<sup>e</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>f</sup> Tested in bacteriostatic sodium chloride 0.9% preserved with benzyl alcohol 0.9%.

<sup>g</sup> Tested in dextrose 5% in Ringer's injection.

<sup>h</sup> Tested in Ringer's injection, lactated.

<sup>i</sup> Lyophilized formulation tested.

<sup>j</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>k</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>l</sup> Tested in dextrose 5% in Ringer's injection, lactated, dextrose 5%, Ringer's injection, lactated, and sodium chloride 0.9%.

<sup>m</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>n</sup> Quinupristin and dalfopristin components combined.

<sup>o</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>p</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>q</sup> Test performed using the formulation WITH edetate disodium.

# Hydromorphone Hydrochloride

AHFS 28:08.08

## Products

Hydromorphone hydrochloride is available in prefilled syringes with each mL of the solution containing hydromorphone hydrochloride 1, 2, or 4 mg with sodium citrate 0.2% and citric acid 0.2%.<sup>3302</sup> Although no preservatives have been added to the formulation, residual amounts of sodium metabisulfite, a reagent used in the purification process of the drug, may be present.<sup>3307</sup>

Hydromorphone hydrochloride also is available in ampuls, cartridges, and prefilled syringes with each mL of the solution containing hydromorphone hydrochloride 1, 2, or 4 mg with sodium lactate 5.4 mg and sodium chloride; lactic acid or sodium hydroxide is used for pH adjustment.<sup>3303</sup> Hydromorphone hydrochloride also is available in 1-mL vials and 20-mL multidose vials with each mL of the solution containing hydromorphone hydrochloride 2 mg with edetate disodium 0.5 mg, methylparaben 1.8 mg, and propylparaben 0.2 mg in water for injection; sodium hydroxide and/or hydrochloric acid may have been added to adjust the pH.<sup>3306</sup>

A high potency formulation of hydromorphone hydrochloride is available packaged in ampuls, prefilled syringes, and single-dose vials; each mL of the solution contains 10 mg of hydromorphone hydrochloride with citric acid 0.2% and sodium citrate 0.2%.<sup>3302 3304 3305</sup> Such formulations are noted to have no added preservatives;<sup>3302 3304 3305</sup> however, sodium metabisulfite may be present in some formulations.<sup>3304</sup>

Care should be taken to avoid confusion between the various standard concentrations of hydromorphone hydrochloride and the more concentrated high potency formulation in order to reduce the risk of medication errors.<sup>3302 3304 3305</sup>

## pH

From 3.5 to 5.5.<sup>3302 3303 3304 3305 3306</sup>

## Trade Name(s)

Dilaudid, Dilaudid-HP

## Administration

Hydromorphone hydrochloride may be administered by subcutaneous, intramuscular, or **slow** direct intravenous injection over at least 2 to 3<sup>3302 3303 3304 3305</sup> or 3 to 5 minutes.<sup>3306</sup> Administration by rapid intravenous injection increases the risk of adverse reactions.<sup>3302 3303 3304 3305 3306</sup>

## Stability

Hydromorphone hydrochloride products should be stored at controlled room temperature and should be protected from light until time of use.<sup>3302 3303 3304 3305 3306</sup> Hydromorphone hydrochloride should not be stored under refrigeration because of possible precipitation or crystallization. Resolubilization at

room temperature or upon warming may be performed without affecting the stability of the drug.<sup>593</sup>

Hydromorphone hydrochloride solution should be visually inspected for particulate matter and discoloration prior to administration.<sup>3302 3303 3304 3305</sup> The solution may develop a slight yellowish discoloration; however, no associated loss of potency has been demonstrated.<sup>3302 3303 3304 3305</sup> If the solution is darker than pale yellow, more than slightly discolored, discolored in any other way, or if it contains a precipitate, it should not be used.<sup>3302 3306</sup> Any unused portions should be discarded.<sup>3302 3303 3304 3305</sup>

Hydromorphone hydrochloride is physically compatible and chemically stable for at least 24 hours in most common large volume parenteral solutions when stored at 25°C protected from light.<sup>3302 3303 3304 3305</sup>

Extemporaneously prepared hydromorphone hydrochloride 10 and 50 mg/mL, stored in 100-mL glass vials or polyvinyl chloride (PVC) bags, exhibited no loss in 42 days at 4 and 23°C.<sup>1394</sup>

## Syringes

In 2015, reports of decreased potency of certain drugs (e.g., hydromorphone hydrochloride) stored in Becton Dickinson syringes for extended periods (i.e., exceeding 24 hours) were confirmed by the manufacturer of these syringes; the cause of this change was later identified to be the inclusion of an alternate rubber stopper in the plunger of certain product lots of syringes.<sup>3029 3036 3037 3039 3041 3042</sup> Decreased potency was not observed when the syringes were filled and used promptly.<sup>3037</sup> Use of the alternate stopper was later discontinued and use of the primary stopper in such syringes was resumed; however, Becton Dickinson states that its general-use syringes are cleared by FDA for immediate use in fluid aspiration and injection and that such syringes, regardless of the stopper material, have not been cleared by FDA for use as a closed-container system.<sup>3391</sup>

Hydromorphone hydrochloride (Knoll) 10 mg/mL undiluted and diluted to 0.1 mg/mL in sodium chloride 0.9% was packaged as 3 mL in 10-mL polypropylene infusion pump syringes (Pharmacia Deltec). No loss occurred over 30 days at 30°C.<sup>1967</sup>

Hydromorphone hydrochloride 1.5 and 80 mg/mL in sodium chloride 0.9% packaged as 20 mL in 30-mL polypropylene syringes was evaluated for physical and chemical stability. Sample solutions were stored for 60 days at 4°C protected from light and 23°C exposed to normal fluorescent light. Other sample solutions were stored frozen at -20°C and at elevated temperature of 37°C for 2 days to simulate more extreme conditions during express shipping. About 2 to 5% loss occurred in 60 days at 4 and 23°C. The frozen and 37°C samples exhibited little change in concentration in 2 days. However, samples stored frozen at -20°C exhibited the formation of microparticulates in the thousands per mL, possibly shed by the syringe components.<sup>2377</sup>

### Implantable Pumps

The stability of hydromorphone hydrochloride 2 (Dilaudid) and 10 (Dilaudid-HP) mg/mL was evaluated in SynchroMed implantable pumps over 16 weeks at 37°C. Little or no drug loss and no adverse effects on the pumps occurred.<sup>2584</sup>

### Central Venous Catheter

Hydromorphone hydrochloride (Knoll) 0.5 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue

Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Tested in sterile water for injection.

<sup>d</sup> Tested in bacteriostatic sodium chloride 0.9% preserved with benzyl alcohol 0.9%.

<sup>e</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>f</sup> Tested in Ringer's injection, lactated.

<sup>g</sup> Lyophilized formulation tested.

<sup>h</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>i</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>j</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>k</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>l</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>m</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>n</sup> Test performed using the formulation WITH edetate disodium.

## Hydroxyethyl Starch 130/0.4 in Sodium Chloride 0.9%

### AHFS 40:12

#### Products

Hydroxyethyl starch 130/0.4 is available as a 6% (6 g/100 mL) injection in sodium chloride 0.9% in 500-mL plastic containers.<sup>3453</sup> The solution also contains sodium hydroxide or hydrochloric acid for pH adjustment.<sup>3453</sup>

#### pH

From 4 to 5.5.<sup>3453</sup>

#### Osmolarity

The calculated osmolarity is 308 mOsm/L.<sup>3453</sup>

#### Tonicity

The injection is an isotonic solution.<sup>3453</sup>

#### Sodium Content

The product provides 77 mEq of sodium per 500-mL container.<sup>3453</sup>

#### Trade Name(s)

Voluven

#### Administration

Hydroxyethyl starch 130/0.4 6% in sodium chloride 0.9% is administered only by intravenous infusion.<sup>3453</sup> Any remaining

solution in partially used containers should be discarded.<sup>3453</sup> The dosage and rate of infusion should be individualized according to the patient's condition and response.<sup>3453</sup> The container is made of nondiethylhexyl phthalate (non-DEHP) plastic and is latex free.<sup>3453</sup> The container itself does not require a vented intravenous administration set, and the manufacturer states that administration of the drug should not be vented.<sup>3453</sup> The product should be inspected for discoloration and particulate matter prior to use.<sup>3453</sup> If the drug is administered by pressure infusion, air should be withdrawn or expelled from the container through the medication/administration port prior to infusion.<sup>3453</sup>

#### Stability

Hydroxyethyl starch 130/0.4 6% in sodium chloride 0.9% is a clear to slightly opalescent colorless to slightly yellow colloidal solution.<sup>3453</sup> The product should be stored at 15 to 25°C and should *not* be frozen.<sup>3453</sup> The bag of solution should not be removed from the overwrap until immediately prior to use.<sup>3453</sup> It should only be administered if the solution is clear and free from particles.<sup>3453</sup> The solution should be administered immediately after insertion of the administration set.<sup>3453</sup>

## Hydroxyzine Hydrochloride

AHFS 28:24.92

### Products

Hydroxyzine hydrochloride is available as a 25-mg/mL solution in 1-mL vials and 10-mL multiple-dose vials. It also is available as a 50-mg/mL solution in 1- and 2-mL single-dose vials and 10-mL multiple-dose vials. Also present in the solutions are benzyl alcohol 0.9% and sodium hydroxide and/or hydrochloric acid to adjust the pH.<sup>1(11/06) 4</sup>

### pH

From 3.5 to 6.<sup>17</sup>

### Administration

Hydroxyzine hydrochloride may be administered undiluted by intramuscular injection only, preferably into the upper outer quadrant of the buttock or the midlateral thigh muscles in adults. In children, the midlateral muscles of the thigh are preferred.<sup>1(11/06) 4</sup>

### Stability

Hydroxyzine should be stored at controlled room temperature and protected from freezing and excessive temperatures.<sup>1(11/06) 4</sup>

## Ibandronate Sodium

AHFS 92:24

### Products

Ibandronate sodium is available as a ready-to-use solution in 3-mL prefilled single-use glass syringes (as a kit with a needle and tubing) and vials containing the equivalent of 3 mg of ibandronate as the free acid.<sup>3136 3137</sup> Sodium chloride, sodium acetate, glacial acetic acid, and water for injection also are present in each syringe or vial.<sup>3136 3137</sup>

### Equivalency

Ibandronate sodium 3.375 mg as the monohydrate is equivalent to 3 mg of ibandronate as the free acid.<sup>3136 3137</sup>

### Trade Name(s)

Boniva

### Administration

Ibandronate sodium is administered intravenously over a period of 15 to 30 seconds.<sup>3136 3137</sup> Ibandronate sodium should *not* be

administered by any other route of administration; care must be taken to avoid intra-arterial or paravenous administration because such administration may result in tissue damage.<sup>3136 3137</sup> Contents of prefilled syringes should be administered only using the 25-gauge needle provided in the prefilled syringe kit.<sup>3136</sup>

### Stability

Ibandronate sodium is a clear, colorless solution.<sup>3136 3137</sup> Intact prefilled syringes and vials should be stored at controlled room temperature.<sup>3136 3137</sup>

Ibandronate sodium solution should be visually inspected for particulate matter or discoloration prior to administration; if particulate matter is present or discoloration occurs, the solution should not be used.<sup>3136 3137</sup> Any unused portion of the solution should be discarded.<sup>3136 3137</sup>

## Ibuprofen

AHFS 28:08.04.92

### Products

Ibuprofen is available as a 100-mg/mL concentrate for injection in single-dose vials containing 800 mg of the drug.<sup>3534</sup> Each mL of the concentrate for injection also contains 78 mg of arginine in water for injection.<sup>3534</sup> **CAUTION: Care should be taken to ensure that the correct drug product, dose, and administration procedures are used and that no confusion with other products (e.g., ibuprofen lysinate [NeoProfen]) occurs.**

The concentrate for injection must be diluted in a compatible diluent prior to administration.<sup>3534</sup> The concentrate for injection should be diluted to a final concentration of 4 mg/mL or less in sodium chloride 0.9%, dextrose 5%, or Ringer's injection, lactated.<sup>3534</sup> For fixed doses of 100, 200, and 400 mg, the manufacturer recommends dilution in at least 100 mL; for fixed doses of 800 mg, the manufacturer recommends dilution in at least 200 mL.<sup>3534</sup> For patients requiring weight-based dosing (e.g., some pediatric patients), the drug should be diluted to a concentration of 4 mg/mL or less.<sup>3534</sup>

Ibuprofen also is available as 4-mg/mL iso-osmotic, ready-to-use solution for infusion in single-dose flexible polypropylene bags containing 800 mg of the drug.<sup>3534</sup> The solution also contains sodium phosphate, sodium hydroxide, and sodium

chloride in water for injection.<sup>3534</sup> The ready-to-use solution for infusion is for use only in those for whom ibuprofen doses of 800 mg are intended.<sup>3534</sup>

### pH

The pH of both the concentrate for injection and the ready-to-use 4-mg/mL solution for infusion is approximately 7.4.<sup>3534</sup>

### Trade Name(s)

Caldolor

### Administration

Ibuprofen injection is intended only for intravenous administration.<sup>3534</sup> Solutions of ibuprofen at concentrations of 4 mg/mL or less are administered by intravenous infusion over at least 30 minutes in adults and over at least 10 minutes in pediatric patients.<sup>3534</sup>

### Stability

Both the concentrate for injection and the ready-to-use solution for infusion are clear and colorless.<sup>3534</sup> Intact vials and bags should be stored at controlled room temperature.<sup>3534</sup> Unused portions should be discarded.<sup>3534</sup>

## Ibuprofen Lysinate

AHFS 28:08.04.92

### Products

Ibuprofen lysinate is available as a preservative-free solution containing in each mL the L-lysine salt of ( $\pm$ ) ibuprofen 17.1 mg (equivalent to ibuprofen 10 mg) with sodium hydroxide or hydrochloric acid to adjust pH during manufacturing in water for injection.<sup>3540</sup> The injection is packaged in single-use 2-mL vials.<sup>3540</sup> **CAUTION: Care should be taken to ensure that the correct drug product, dose, and administration procedures are used and that no confusion with other products (e.g., ibuprofen [Caldolor]) occurs.**

### pH

The pH of the solution is adjusted to 7.<sup>3540</sup>

### Trade Name(s)

NeoProfen

### Administration

Ibuprofen lysinate is administered intravenously using the intravenous port that is nearest the insertion site following dilution of the drug to a suitable volume with dextrose or saline infusion

solution.<sup>3540</sup> The drug should be prepared and administered within 30 minutes of preparation by intravenous infusion over 15 minutes taking care to avoid extravasation.<sup>3540</sup>

The manufacturer states that administration of the drug using an umbilical arterial line has not been evaluated.<sup>3540</sup>

### Stability

Intact vials of ibuprofen lysinate should be stored at controlled room temperature protected from light.<sup>3540</sup> The manufacturer recommends retaining the vials in their carton until use.<sup>3540</sup>

After dilution to an appropriate volume with dextrose or saline intravenous infusion solution, ibuprofen lysinate should be administered within 30 minutes over a period of 15 minutes.<sup>3540</sup> Any remaining solution in the single-use vials should be discarded because no antimicrobial preservative is present.<sup>3540</sup> The manufacturer recommends not administering ibuprofen lysinate into a line running a total parenteral nutrition (TPN) admixture; the TPN should be interrupted if necessary for 15 minutes both before and after administering ibuprofen lysinate maintaining line patency using dextrose or saline infusion solution.<sup>3540</sup>

## Ibutilide Fumarate

AHFS 24:04.04.20

### Products

Ibutilide fumarate is available in single-use 10-mL vials containing 1 mg of the drug.<sup>3193</sup> Each mL of solution contains 0.1 mg of ibutilide fumarate and also contains sodium acetate trihydrate 0.189 mg, sodium chloride 8.9 mg, and sodium hydroxide and/or hydrochloric acid to adjust the pH in water for injection.<sup>3193</sup>

### Equivalency

Ibutilide fumarate 0.1 mg is equivalent to 0.087 mg of ibutilide as the free base.<sup>3193</sup>

### pH

The pH of the 0.1-mg/mL solution has been adjusted to approximately 4.6.<sup>3193</sup>

### Tonicity

Ibutilide fumarate injection is isotonic.<sup>3193</sup>

### Trade Name(s)

Corvert

### Administration

Ibutilide fumarate is administered intravenously as an infusion over 10 minutes.<sup>3193</sup> The drug may be administered undiluted or diluted in 50 mL of dextrose 5% or sodium chloride 0.9%.<sup>3193</sup>

### Stability

Ibutilide fumarate injection is a clear, colorless solution.<sup>3193</sup> Intact vials should be stored at controlled room temperature and kept in the carton until use.<sup>3193</sup>

## Compatibility Information

## Idarubicin Hydrochloride

### AHFS 10:00

#### Products

Idarubicin hydrochloride is available as a 1-mg/mL red-orange preservative-free solution in single-use vials containing 5, 10, and 20 mL.<sup>2964 2965</sup> In addition to the drug, each mL also contains glycerin 25 mg in water for injection;<sup>2964 2965</sup> hydrochloric acid<sup>2964</sup> or hydrochloric acid and/or sodium hydroxide<sup>2965</sup> is used to adjust pH.<sup>2964 2965</sup>

#### pH

The pH of idarubicin hydrochloride has been adjusted to a target of 3.5.<sup>2964 2965</sup>

#### Tonicity

Idarubicin hydrochloride injection is isotonic.<sup>2964 2965</sup>

#### Trade Name(s)

Idamycin PFS

#### Administration

Idarubicin hydrochloride should be administered by slow intravenous injection over 10 to 15 minutes into the tubing of a running infusion of sodium chloride 0.9% or dextrose 5%.<sup>2964 2965</sup> The manufacturer recommends that the tubing be attached to a butterfly needle or other suitable device, inserted preferably into a large vein.<sup>2964 2965</sup> The drug should not be given subcutaneously or intramuscularly, and extravasation should be avoided to prevent severe tissue necrosis.<sup>2964 2965</sup> Care should be exercised during dose preparation to avoid inadvertent skin contact with the drug.<sup>2964 2965</sup>

## Compatibility Information

### Solution Compatibility

#### Idarubicin HCl

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 5% in sodium chloride 0.9%		FA	10 mg	No loss in 72 hr at room temperature protected from light. Less than 10% loss in 6 hr at room temperature exposed to light	1493	C
Dextrose 5%		FA	100 mg	Up to 5% loss in 4 weeks at 25°C in the dark	1007	C
Dextrose 5%		FA	10 mg	No loss in 72 hr at room temperature protected from light. Less than 10% loss in 6 hr at room temperature exposed to light	1493	C
Ringer's injection, lactated		FA	100 mg	Up to 5% loss in 4 weeks at 25°C in the dark	1007	C
Sodium chloride 0.9%		FA	100 mg	Up to 5% loss in 4 weeks at 25°C in the dark	1007	C
Sodium chloride 0.9%		FA	10 mg	No loss in 72 hr at room temperature protected from light. Less than 10% loss in 6 hr at room temperature exposed to light	1493	C

#### Stability

Idarubicin hydrochloride in intact vials should be stored under refrigeration at 2 to 8°C and protected from light.<sup>2964 2965</sup> Leaving the vials in the carton until the time of use is recommended.<sup>2964 2965</sup>

Idarubicin hydrochloride (Farmitalia) 0.07 mg/mL diluted in sodium chloride 0.9% and stored at 22°C did not exhibit an antimicrobial effect on the growth of 4 organisms (*Enterococcus faecium*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Candida albicans*) inoculated into the solution. Viability was maintained for periods of 48 to 120 hours. The author recommended that diluted solutions of idarubicin hydrochloride be stored under refrigeration whenever possible and that the potential for microbiological growth be considered when assigning expiration periods.<sup>2160</sup>

#### pH Effects

Idarubicin hydrochloride in prolonged contact with alkaline solutions will undergo decomposition.<sup>1368 2964 2965</sup>

#### Light Effects

Dilute solutions (0.01 mg/mL) of idarubicin hydrochloride are light sensitive, undergoing some degradation with exposure to light over periods greater than 6 hours.<sup>1368</sup> However, the manufacturers suggest that no special precautions are necessary to protect freshly prepared solutions for administration.<sup>1369</sup>

#### Sorption

Idarubicin hydrochloride is compatible with PVC, glass, and polypropylene.<sup>1369</sup>

## Idarucizumab

AHFS 20:28.92

### Products

Idarucizumab is available as a preservative-free solution in single-use vials in packs containing 2 vials.<sup>3094</sup> Each 50-mL vial contains idarucizumab 2.5 g, glacial acetic acid 10.05 mg, polysorbate 20 10 mg, sodium acetate trihydrate 147.35 mg, sorbitol 2004.2 mg, and water for injection.<sup>3094</sup>

Idarucizumab should be visually inspected for particulate matter or discoloration prior to administration.<sup>3094</sup>

### pH

From 5.3 to 5.7.<sup>3094</sup>

### Osmolality

Idarucizumab is isotonic with an osmolality of 270 to 330 mOsm/kg.<sup>3094</sup>

### Trade Name(s)

Praxbind

### Administration

Idarucizumab should be administered intravenously by infusion or by bolus injection.<sup>3094</sup> For intravenous infusion, each

2.5-g vial should be infused consecutively to total 5 g.<sup>3094</sup> The drug also has been administered as a single infusion of 5 g over 5 minutes in some clinical studies.<sup>3094</sup>

For intravenous bolus injection, a syringe should be used to withdraw and consecutively inject the contents of 2 vials.<sup>3094</sup>

If an existing intravenous line is used for idarucizumab administration, the line must be flushed with sodium chloride 0.9% prior to administration.<sup>3094</sup>

### Stability

Intact vials should be stored at 2 to 8°C.<sup>3094</sup> Idarucizumab is a colorless to slightly yellow, clear to slightly opalescent solution.<sup>3094</sup> Vials should not be frozen or shaken.<sup>3094</sup>

Unopened vials of idarucizumab may be stored at 25°C for up to 48 hours when stored in the original package to protect from light or for up to 6 hours when exposed to light.<sup>3094</sup>

Administration of idarucizumab should begin promptly (within 1 hour) once the solution has been withdrawn from the vial.<sup>3094</sup>

### AHFS 10:00

### Products

Ifosfamide is available in vials containing 1 or 3 g of drug. Reconstitute the ifosfamide with 20 or 60 mL of sterile water for injection or bacteriostatic water for injection (parabens or benzyl alcohol), respectively, to yield a 50-mg/mL solution.<sup>1(7/07)</sup>

### pH

Approximately 6.<sup>72</sup>

### Trade Name(s)

Ifex

### Administration

Ifosfamide is administered by slow intravenous infusion over a minimum of 30 minutes diluted to a concentration between 0.6 and 20 mg/mL.<sup>1(7/07)</sup> <sup>4</sup> Ifosfamide also has been administered by continuous intravenous infusion.<sup>4</sup> To prevent bladder toxicity, mesna and at least 2 L/day of fluid should be given.<sup>1(7/07)</sup> <sup>4</sup>

### Stability

Intact vials of ifosfamide should be stored at controlled room temperature and protected from temperatures above 30°C.<sup>1(7/07)</sup> Ifosfamide may liquify at temperatures above 35°C.<sup>72</sup>

The reconstituted solution is stated to be chemically and physically stable for 7 days at 30°C and for up to 6 weeks under refrigeration.<sup>4</sup> <sup>72</sup> Because of microbiological concerns, the manufacturer recommends storage under refrigeration and use in 24 hours for reconstituted or diluted ifosfamide solutions.<sup>1(7/07)</sup>

Ifosfamide (Boehringer-Ingelheim) 80 mg/mL in sodium chloride 0.9% exhibited about 7% loss in 9 days at 37°C in the dark.<sup>1494</sup>

Reconstitution to an ifosfamide concentration of 100 mg/mL with benzyl alcohol-preserved bacteriostatic water for injection resulted in a turbid mixture, separating into 2 distinct liquid phases. The separate phases dissolved completely, with no loss of drug or preservative, when diluted to about 60 mg/mL or less.<sup>1289</sup>

### pH Effects

Ifosfamide exhibits maximum solution stability in the pH range of 4 to 10; the rate of decomposition is essentially the same over this pH range. At pH values less than 4 and above 10, increased rates of decomposition have been observed.<sup>2002</sup> <sup>2401</sup>

### Syringes

Ifosfamide 0.6 and 20 mg/mL in dextrose 5%, lactated Ringer's injection, sodium chloride 0.9%, and sterile water for injection in polypropylene syringes (Becton Dickinson) is physically and chemically stable for at least 24 hours at 30°C.<sup>1496</sup>

### Ambulatory Pumps

Ifosfamide (Asta Medica) 20 mg/mL and mesna (Asta Medica) 20 mg/mL in water for injection were evaluated for stability and compatibility in polyvinyl chloride (PVC) reservoirs for Graseby 9000 ambulatory pumps. The solutions were physically compatible and analysis found about 3% ifosfamide and 9% mesna loss in 7 days at 37°C. About 2% or less loss of both drugs was found after 14 days at 4°C. Furthermore, weight losses due to moisture loss were minimal.<sup>2288</sup>

# Imipenem–Cilastatin Sodium

AHFS 8:12.07.08

## Products

Imipenem–cilastatin sodium for intravenous use is available as a fixed combination of equal quantities of both drugs. The combination is provided in vials and infusion bottles containing 250 or 500 mg of each drug with sodium bicarbonate 10 or 20 mg, respectively.<sup>1(8/06)</sup>

The contents of a vial should be reconstituted with about 10 mL of a compatible diluent from a 100-mL infusion container and shaken well to form a suspension. Diluents containing benzyl alcohol should not be used to reconstitute the drug for use in neonates and small pediatric patients. The suspension must be transferred to the remaining solution in the infusion container for dilution. The suspension is *not* for direct injection. The procedure is then repeated: a 10-mL aliquot from the admixture is added to the vial and, once again, returned to the infusion admixture. This procedure ensures that all of the vial contents are transferred. The admixture should be agitated until it is clear to yield either a 2.5- or 5-mg/mL concentration, depending on the vial content. The admixture should *not* be heated to aid dissolution.<sup>1(8/06) 4</sup>

ADD-Vantage vials of imipenem–cilastatin sodium should be prepared with 100 mL of dextrose 5% or sodium chloride 0.9% in ADD-Vantage diluent bags.<sup>1(8/06) 4</sup>

The 250- and 500-mg piggyback infusion bottles should be reconstituted with 100 mL of compatible diluent and shaken until clear to yield 2.5- and 5-mg/mL concentrations, respectively.<sup>1(8/06) 4</sup>

Imipenem–cilastatin sodium for intramuscular use is available in vials containing 500 or 750 mg of each component. The vials should be reconstituted with 2 or 3 mL, respectively, of lidocaine hydrochloride 1% (without epinephrine) and agitated to form a suspension. This intramuscular formulation is not for intravenous use.<sup>1(8/06) 4</sup>

## pH

The intravenous product is buffered to pH 6.5 to 8.5.<sup>1(8/06)</sup>

## Osmolarity

When reconstituted and diluted as directed by the manufacturer, the osmolarity of the intravenous admixture approximates that of the diluent.<sup>4</sup>

## Sodium Content

The 250- and 500-mg intravenous vials contain 0.8 mEq (18.8 mg) and 1.6 mEq (37.5 mg) of sodium, respectively. The 500- and 750-mg intramuscular vials contain 1.4 mEq (32 mg) and 2.1 mEq (48 mg) of sodium, respectively.<sup>1(8/06) 4</sup>

## Trade Name(s)

Primaxin I.V., Primaxin I.M.

## Administration

Imipenem–cilastatin sodium for intravenous use is administered by intermittent intravenous infusion at a concentration not exceeding 5 mg/mL. Infusion periods vary from 20 to 60 minutes, depending on the dose. The intramuscular formulation should be injected deeply into a large muscle mass. Suspensions of either formulation should not be given intravenously.<sup>1(8/06) 4</sup>

## Stability

The product should be stored below 25°C.<sup>1(8/06) 4</sup>

Reconstituted as directed, intravenous solutions are colorless to yellow but may become a deeper yellow over time. Intramuscular suspensions are white to light tan. The manufacturer indicates that stability is not affected by color variations within this range,<sup>1(8/06)</sup> but the solutions should be discarded if they darken to brown.<sup>4</sup> Intramuscular suspensions prepared with lidocaine hydrochloride (without epinephrine) should be used within 1 hour.<sup>1(8/06) 4</sup>

In solution, imipenem is substantially less stable than cilastatin and is the determining factor in the overall stability of the combination product. Reconstitution results in solutions that are stable for 4 hours at room temperature or 24 hours under refrigeration at 4°C.<sup>1(8/06)</sup>

Imipenem degradation kinetics were determined for a 2.5-mg/mL solution in sodium chloride 0.9%. The degradation rates were temperature dependent, with a half-life of over 44 hours at 2°C dropping to 6 hours at 25°C and to 2 hours at 37°C. The decomposition was consistent with hydrolysis, and the loss of antimicrobial activity suggests cleavage of the  $\beta$ -lactam ring.<sup>1272</sup>

## Concentration Effects

In one study, solutions of imipenem–cilastatin in sterile water for injection at concentrations exceeding 8 g/L (not specified whether concentration refers to single component or combined components) resulted in precipitation.<sup>3105</sup>

## pH Effects

Imipenem is inactivated at acidic or alkaline pH but is more stable at neutral pH.<sup>4</sup> The pH range of maximum stability appears to be 6.5 to 7.5, with increasing rates of decomposition occurring as the pH moves away from this range.<sup>1273</sup> At a pH of about 4, the half-life of imipenem is about 35 minutes.<sup>2166</sup>

## Freezing Solutions

The manufacturer recommends that imipenem–cilastatin solutions not be frozen.<sup>1(8/06)</sup> At concentrations of 250 and 500 mg/100 mL in sodium chloride 0.9%, imipenem losses of around 15% occurred in 1 week when frozen at –20 and –10°C.<sup>1141</sup> Freezing solutions at

temperatures above  $-70^{\circ}\text{C}$  offers no stability advantage over refrigerated storage<sup>1141</sup> and results in decomposition of imipenem in a manner similar to ampicillin.<sup>4</sup>

### Effects of Solution Components

Dextrose exerts an adverse effect on the stability of imipenem. Dextrose 5 and 10% reduced the time to 10% decomposition by about one-half compared to sterile water. Sodium chloride content increases imipenem stability because of a positive kinetic salt effect similar to other  $\beta$ -lactam antibiotics. Both lactate and bicarbonate anions attack the  $\beta$ -lactam ring and decrease imipenem stability.<sup>1141</sup>

### Elastomeric Reservoir Pumps

Imipenem–cilastatin sodium (Merck) 5 mg/mL in both dextrose 5% and sodium chloride 0.9% was evaluated for binding

potential to natural rubber elastomeric reservoirs (Baxter). Less than 1% binding was found after storage for 2 weeks at  $35^{\circ}\text{C}$  with gentle agitation.<sup>2014</sup>

### Central Venous Catheter

Imipenem–cilastatin (MSD) 2 mg/mL in sodium chloride 0.9% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>d</sup> Tested in dextrose 5% with albumin human 2 mg/mL.

<sup>e</sup> Lyophilized formulation tested.

<sup>f</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>g</sup> Injected via Y-site into an administration set running azithromycin.

<sup>h</sup> Imipenem component. Imipenem in a 1:1 fixed-ratio concentration with cilastatin.

<sup>i</sup> Not specified whether concentration refers to single component or combined components.

<sup>j</sup> Quinupristin and dalfopristin components combined.

<sup>k</sup> Salt not specified.

<sup>l</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>m</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>n</sup> Ceftazidime component. Ceftazidime in a 4:1 fixed-ratio concentration with avibactam.

<sup>o</sup> Tested in dextrose 5%, sodium chloride 0.9%, and Ringer's injection, lactated.

<sup>p</sup> Test performed using the formulation WITH edetate disodium.

<sup>q</sup> Run at 25 mL/hr with dextrose 5% run at 83 mL/hr.

<sup>r</sup> Run at 100 mL/hr.

## Imipenem–Cilastatin Sodium–Relebactam

AHFS 8:12.07.08

### Products

The fixed combination of imipenem–cilastatin sodium–relebactam is available as a powder for injection in single-dose vials containing 1.25 g (imipenem 500 mg [as the monohydrate], cilastatin 500 mg [as the sodium salt], relebactam 250 mg [as the monohydrate]) along with sodium bicarbonate 20 mg to adjust the pH.<sup>3505</sup>

To prepare the fixed combination for administration, infusion bags containing 100 mL of a compatible diluent should be used; if an infusion bag containing 100 mL of a compatible diluent is not available, 100 mL of a compatible diluent may be transferred into an empty infusion bag.<sup>3505</sup> Twenty mL (as two 10-mL aliquots) of the compatible diluent should be removed from the infusion bag.<sup>3505</sup> The contents of one 1.25-g vial should be reconstituted initially with one 10-mL aliquot of the compatible diluent (withdrawn from the infusion bag) and the vial should be shaken well.<sup>3505</sup> The resulting suspension should then be transferred into the infusion bag containing the remaining 80 mL of diluent.<sup>3505</sup> The second 10-mL aliquot of the compatible diluent should then be added to the vial and shaken well to ensure complete transfer of any remaining vial contents; the resulting suspension should be transferred to the infusion bag to total 100 mL and the infusion bag should be agitated until the infusion solution is clear.<sup>3505</sup>

The manufacturer's instructions for preparing various doses of imipenem–cilastatin–relebactam from the infusion solution are as follows:<sup>3505</sup>

For 1.25 g (imipenem 500 mg, cilastatin 500 mg, relebactam 250 mg), do not remove any volume from the prepared infusion bag; the solution delivers a 1.25-g dose in 100 mL.

For 1 g (imipenem 400, cilastatin 400 mg, relebactam 200 mg), remove and discard 20 mL from the prepared infusion bag; the remaining solution (i.e., 80 mL) delivers a 1-g dose.

For 0.75 g (imipenem 300 mg, cilastatin 300 mg, relebactam 150 mg), remove and discard 40 mL from the prepared infusion bag; the remaining solution (i.e., 60 mL) delivers a 0.75-g dose.

For 0.5 g (imipenem 200 mg, cilastatin 200 mg, relebactam 100 mg), remove and discard 60 mL from the prepared infusion bag; the remaining solution (i.e., 40 mL) delivers a 0.5-g dose.

### Equivalency

In imipenem–cilastatin sodium–relebactam, cilastatin sodium 531 mg is equivalent to 500 mg of cilastatin.<sup>3505</sup>

### pH

Diluted solutions of imipenem–cilastatin–relebactam for infusion have a pH ranging from 6.5 to 7.6.<sup>3505</sup>

### Sodium Content

Each 1.25-g vial of this fixed combination contains 37.5 mg (1.6 mEq) of sodium.<sup>3505</sup>

### Trade Name(s)

Recarbrio

### Administration

Imipenem–cilastatin sodium–relebactam is administered by intravenous infusion over 30 minutes after reconstitution and dilution.<sup>3505</sup>

### Stability

Imipenem–cilastatin sodium–relebactam is a white to light yellow lyophilized powder that forms a clear, colorless to yellow solution upon reconstitution and dilution; variations in color within this range do not affect the potency of the product.<sup>3505</sup> Intact vials of imipenem–cilastatin sodium–relebactam should be stored at controlled room temperature.<sup>3505</sup>

Diluted solutions of imipenem–cilastatin–relebactam for infusion should be visually inspected for particulate matter and discoloration prior to administration.<sup>3505</sup> Solutions that are discolored and those in which visible particles are observed should be discarded.<sup>3505</sup>

The diluted solution for infusion is stable for 2 hours at room temperature up to 30°C or for 24 hours at 2 to 8°C.<sup>3505</sup>

### Freezing Solutions

The manufacturer states that solution of imipenem–cilastatin sodium–relebactam should not be frozen.<sup>3505</sup>

## Immune Globulin Human

### AHFS 80:04

### Products

Immune globulin human products may be formulated for intravenous or subcutaneous infusion or for intramuscular injection; the product labeling must be consulted for details on the specific product, including instructions for preparation, administration, and storage.

Immune globulin human products for intravenous administration include: Bivigam (Biotest); Carimune NF (CSL Behring); Flebogamma DIF (5 or 10%, Grifols); Gammagard S/D (Baxter); Gammagard Liquid (Baxter); Gammaked (Grifols); Gammaplex (BPL); Gamunex-C (Grifols); Octagam (5 or 10%, Octapharma); and Privigen (CSL Behring).<sup>3053 3054 3055 3056 3058 3059 3060 3061 3062 3065 3066 3067</sup>

Immune globulin human products intended exclusively for subcutaneous infusion include: Cuvitru (Baxalta), Hizentra (CSL Behring) and HyQvia (Baxter).<sup>3063 3064 3240</sup> In addition, several of the intravenous immune globulin human preparations also may be administered by subcutaneous infusion for certain indications; these products include Gammagard Liquid (Baxter); Gammaked (Grifols); and Gamunex-C (Grifols).<sup>3059 3060 3062</sup>

GamaSTAN S/D (Grifols) immune globulin human is labeled solely for administration by intramuscular injection.<sup>3057</sup>

#### *Immune Globulin Human Products for Intravenous Administration Only*

Immune globulin human intravenous is available from a number of manufacturers in both liquid and lyophilized powder forms that are prepared with varying manufacturing processes and excipients, resulting in different physicochemical properties for each formulation.<sup>3075</sup> Protein concentrations of 5 and 10% are available in liquid forms.<sup>3075</sup> Lyophilized preparation vial sizes vary by product, but typically contain between 3 and 12 g of protein.<sup>3054 3058</sup> Lyophilized preparations require reconstitution with the diluents and volumes specified by the manufacturers and typically result in protein concentrations of 3 to 12%.<sup>3054 3058 3075</sup>

Bivigam (Biotest) is available as a 10% solution in 50- and 100-mL single-use vials.<sup>3053</sup> The drug also contains sodium chloride 0.1 to 0.14 M (approximately 5.8 to 8.2 mg/mL), glycine 0.2 to 0.29 M (approximately 15 to 21.8 mg/mL), and polysorbate 80 0.15 to 0.25% in water for injection.<sup>3053</sup> The concentration of IgA present in the formulation does not exceed 200 mcg/mL.<sup>3053</sup>

Carimune NF (CSL Behring) is available as a lyophilized powder in single-use vials containing 3, 6, and 12 g of protein.<sup>3054</sup> The drug should be reconstituted with sodium chloride 0.9%, dextrose 5%, or sterile water for injection in the amounts shown in Table 1.<sup>3054</sup>

**Table 1. Reconstitution of Carimune NF<sup>3054</sup>**

Target Concentration	Volume of Diluent to be Added		
	3-g Vial	6-g Vial	12-g Vial
3%	100 mL	200 mL	<sup>a</sup>
6%	50 mL	100 mL	200 mL
9%	33 mL	66 mL	132 mL
12%	25 mL	50 mL	100 mL

<sup>a</sup> Container not large enough to permit concentration.

Vials of Carimune NF also contain sucrose 1.67 g and less than 20 mg of sodium chloride per gram of protein.<sup>3054</sup> Trace amounts of IgA and IgM are present.<sup>3054</sup>

Flebogamma DIF (Grifols) is available as a 5% solution in 10-, 50-, 100-, 200-, and 400-mL single-use vials<sup>3055</sup> and as a 10% solution in 50-, 100-, and 200-mL single-use vials.<sup>3056</sup> Both strengths contain D-sorbitol 5 g in 100 mL of water for injection, trace amounts of sodium, and no greater than 3 or 6 mg/mL of polyethylene glycol in the 5 or 10% preparations, respectively.<sup>3055 3056</sup> The 5% solutions typically contain less than 50 mcg/mL of IgA,<sup>3055</sup> and the 10% solutions typically contain less than 100 mcg/mL.<sup>3056</sup> Both strengths contain trace amounts of IgM.<sup>3055 3056</sup>

Gammagard S/D (Baxter) is available in a kit containing 5 or 10 g of lyophilized immune globulin human in a single-use bottle, a diluent bottle containing sterile water for injection, a transfer device, and an administration set with an integral airway and a 15- $\mu$ m filter.<sup>3058</sup> To produce the desired concentration, the powder must be reconstituted with an appropriate amount of the provided diluent.<sup>3058</sup> Before the provided transfer device is attached to the diluent vial, however, the amounts of diluent shown in Table 2 must be *removed* from the vial depending on the target concentration; the amount remaining in the vial is then used to reconstitute the lyophilized immune globulin human using the transfer device.<sup>3058</sup> The manufacturer's prescribing information should be consulted for specific instructions.<sup>3058</sup>

**Table 2. Reconstitution of Gammagard S/D<sup>3058</sup>**

Target Concentration	Volume of Diluent to be <i>Removed</i> from Diluent Vial	
	5-g Vial	10-g Vial
5%	0 mL <sup>a</sup>	0 mL <sup>a</sup>
10%	48 mL	96 mL

<sup>a</sup> Do not remove any diluent from the diluent vial to prepare a 5% solution.

When Gammagard S/D is reconstituted as directed, each mL of the resulting 5% solution also contains sodium chloride 8.5 mg, albumin human 3 mg, glycine 22.5 mg, glucose 20 mg, polyethylene glycol 2 mg, tri-n-butyl phosphate (TNBP) 1 mcg, octoxynol 9 1 mcg, and polysorbate 80 100 mcg.<sup>3058</sup> (A 10% solution contains twice the concentration of these excipients per mL contained in the 5% solution.<sup>3058</sup>) Less than 1 mcg/mL of IgA is present in the 5% solution and less than 2 mcg/mL is present in the 10% solution.<sup>3058</sup> Trace amounts of IgM also are present.<sup>3058</sup>

Gammaplex (BPL) is available as a 5% solution in 50-, 100-, 200-, and 400-mL single-use bottles.<sup>3061</sup> The formulation also contains 5 g D-sorbitol in 100 mL of buffer solution, which contains glycine 0.6 g, sodium acetate 0.2 g, sodium chloride 0.3 g, and polysorbate 80 approximately 5 mg.<sup>3061</sup> IgA is present at a concentration of less than 10 mcg/mL.<sup>3061</sup>

Octagam (Octapharma) 5 and 10% solutions are available in 20-, 50-, 100-, and 200-mL single-use bottles.<sup>3065 3066</sup> The 5% solution also is available in 500-mL single-use bottles.<sup>3065</sup> To prevent coring, needles larger than 16 gauge should not be used with either strength of the drug.<sup>3065 3066</sup> Each mL of the 5% formulation also contains maltose 100 mg, octoxynol (TRITON X-100) no greater than 5 mcg, TNBP no greater than 1 mcg, and sodium no greater than 0.03 mmol in water for injection.<sup>3065</sup> Each mL of the 10% formulation also contains maltose 90 mg and sodium no greater than 0.03 mmol.<sup>3066</sup> No greater than 200 mcg/mL of IgA and 100 mcg/mL of IgM are present in the 5% solution.<sup>3065</sup> In the 10% formulation, IgA is present at an average concentration of 106 mcg/mL with even lesser amounts of IgM.<sup>3066</sup>

Privigen (CSL Behring) is available as a 10% solution in 50-, 100-, 200-, and 400-mL single-use vials.<sup>3067</sup> Each mL of the formulation also contains L-proline 0.25 mmol (range: 0.21 to 0.29 mmol) and trace amounts of sodium.<sup>3067</sup> The concentration of IgA present in the formulation does not exceed 25 mcg/mL.<sup>3067</sup>

#### *Immune Globulin Human Products for Intravenous or Subcutaneous Administration*

Several immune globulin human preparations (e.g., Gammagard Liquid, Gammaked, and Gamunex-C) may be administered by intravenous or subcutaneous infusion depending on the specific indication.<sup>3059 3060 3062</sup>

Gammagard Liquid (Baxter) is available as a 10% solution in 10-, 25-, 50-, 100-, 200-, and 300-mL single-use bottles.<sup>3059</sup> The formulation also contains glycine 0.25 M (approximately 18.8 mg/mL).<sup>3059</sup> IgA is present at an average concentration of 37 mcg/mL; trace amounts of IgM are present.<sup>3059</sup>

Gammaked and Gamunex-C (both manufactured by Grifols) are available as 10% solutions in 10-, 25-, 50-, 100-, and 200-mL single-use vials.<sup>3060 3062</sup> Gamunex-C also is available in 400-mL single-use vials.<sup>3062</sup> Only 18-gauge needles should be used to penetrate the stopper of Gammaked or Gamunex-C 10-mL vials; for vials containing 25 mL or more, 16-gauge needles or dispensing pins should be used.<sup>3060 3062</sup> Both products also contain glycine 0.16 to 0.24 M (approximately 12 to 18 mg/mL)

and residual caprylate concentrations no greater than 216 mg/mL (1.3 mmol/L).<sup>3060 3062</sup> IgA is present at an average concentration of 46 mcg/mL; trace amounts of IgM also are present.<sup>3060 3062</sup>

#### *Immune Globulin Human Products for Subcutaneous Administration*

Some immune globulin human products are intended only for administration by subcutaneous infusion.<sup>3063 3064 3240</sup>

Cuvitru (Baxalta) is available as a 20% solution in 5-, 10-, 20-, and 40-mL single-use vials for subcutaneous use only.<sup>3240</sup> Each vial also contains glycine 0.25 M.<sup>3240</sup> IgA is present at an average concentration of 80 mcg/mL.<sup>3240</sup>

Hizentra (CSL Behring) is available as a 20% solution in 5-, 10-, 20-, and 50-mL single-use vials for subcutaneous use only.<sup>3063</sup> Each mL of the formulation also contains L-proline 0.25 mmol (range: 0.21 to 0.29 mmol), polysorbate 80 0.008 to 0.03 mg, and trace amounts of sodium.<sup>3063</sup> The concentration of IgA present in the formulation does not exceed 50 mcg/mL.<sup>3063</sup>

HyQvia (Baxter) is available as a 10% solution in 25-, 50-, 100-, 200-, and 300-mL single-use vials; each vial is packaged with a vial containing recombinant human hyaluronidase 160 units/mL.<sup>3064</sup> The 2 vials should *not* be mixed; they are intended for *sequential* subcutaneous use only.<sup>3064</sup> The immune globulin human vial also contains glycine 0.25 M (approximately 18.8 mg/mL); IgA is present at an average concentration of less than 37 mcg/mL, and trace amounts of IgM also are present.<sup>3064</sup> Each mL of the recombinant human hyaluronidase solution also contains sodium chloride 8.5 mg, sodium phosphate dibasic dihydrate 1.78 mg, human albumin 1 mg, edetate disodium dihydrate 1 mg, and calcium chloride dihydrate 0.4 mg; sodium hydroxide 0.17 mg has been added for pH adjustment.<sup>3064</sup>

#### *Immune Globulin Human Products for Intramuscular Administration*

GamaSTAN S/D (Grifols) is available as a 15 to 18% solution in 2- and 10-mL single-use vials for intramuscular use only.<sup>3057</sup> The formulation also contains glycine 0.21 to 0.32 M (approximately 15.8 to 24 mg/mL).<sup>3057</sup> IgA presence and/or concentration is not specified in the prescribing information.<sup>3057</sup>

#### *Reconstitution of Lyophilized Immune Globulin Human*

To reconstitute a lyophilized immune globulin human powder, the diluent specified by the manufacturer should be added and then the vial or bottle should be rotated or swirled to dissolve particles.<sup>3054 3058</sup> Foaming, which has been noted to be very slow to subside in some products,<sup>3054</sup> results from shaking and should be avoided<sup>3054 3058</sup> because it may impede dissolution.<sup>1499</sup> In general, liquid and reconstituted immune globulin human products should not be shaken.<sup>3053 3054 3058 3059 3060 3061 3062 3063 3064 3067</sup>

Reconstitution of Sandoglobulin (no longer commercially available in the US) with dextrose 5% has resulted in extended dissolution times of 75 and 135 minutes for the 3 and 6% solutions, respectively. With sodium chloride 0.9%, dissolution occurs over a few minutes; exceptional cases take up to 20 minutes.<sup>1498</sup>

## pH

Bivigam: From 4 to 4.6.<sup>3053</sup>  
 Carimune NF: From 6.4 to 6.8.<sup>3054</sup>  
 Cuvitru: From 4.6 to 5.1.<sup>3240</sup>  
 Flebogamma DIF: From 5 to 6.<sup>3055 3056</sup>  
 GamaSTAN: From 6.4 to 7.2.<sup>3057</sup>  
 Gammagard Liquid: From 4.6 to 5.1.<sup>3059</sup>  
 Gammagard S/D: From 6.4 to 7.2.<sup>3058</sup>  
 Gammaked: From 4 to 4.5.<sup>3060</sup>  
 Gammaplex: From 4.8 to 5.1.<sup>3061</sup>  
 Gamunex-C: From 4 to 4.5.<sup>3062</sup>  
 Hizentra: From 4.6 to 5.2.<sup>3063</sup>  
 HyQvia: From 4.6 to 5.1.<sup>3064</sup>  
 Octagam 5%: From 5.1 to 6;<sup>3065</sup> Octagam 10%: From 4.5 to 5.<sup>3066</sup>  
 Privigen: From 4.6 to 5.<sup>3067</sup>

## Osmolality

Carimune NF: Following reconstitution of the Carimune NF formulation of immune globulin human to targeted concentrations of 3, 6, 9, or 12%, the calculated osmolality of the solution varied with the diluent used.<sup>3054</sup> (See Table 3.)

**Table 3. Calculated osmolality of reconstituted Carimune NF (CSL Behring)<sup>3054</sup>**

Diluent	Osmolality (mOsm/kg)			
	Carimune NF 3%	Carimune NF 6%	Carimune NF 9%	Carimune NF 12%
Dextrose 5%	444	636	828	1020
Sodium chloride 0.9%	498	690	882	1074
Sterile water for injection	192	384	576	768

Cuvitru: 280 to 292 mOsm/kg.<sup>3240</sup>  
 Flebogamma DIF 5 and 10%: 240 to 370 mOsm/kg.<sup>3055 3056</sup>  
 Gammagard Liquid: 240 to 300 mOsm/kg.<sup>3059</sup>  
 Gammaked: 258 mOsm/kg.<sup>3060</sup>  
 Gammaplex: Typically 420 to 500 mOsm/kg.<sup>3061</sup> Not less than 240 mOsm/kg.<sup>3061</sup>  
 Gamunex-C: 258 mOsm/kg.<sup>3062</sup>  
 HyQvia: 240 to 300 mOsm/kg.<sup>3064</sup>  
 Octagam 5 and 10%: 310 to 380 mOsm/kg.<sup>3065 3066</sup>  
 Privigen: Approximately 320 mOsm/kg (range: 240 to 440 mOsm/kg).<sup>3067</sup>

## Trade Name(s)

Bivigam, Carimune NF, Cuvitru, Flebogamma DIF, GamaSTAN S/D, Gammagard Liquid, Gammagard S/D, Gammaked, Gammaplex, Gamunex-C, Hizentra, HyQvia, Octagam, Privigen

## Administration

Immune globulin human may be administered by intravenous infusion,<sup>3053 3054 3055 3056 3058 3059 3060 3061 3062 3065 3066 3067</sup> subcutaneous infusion using an infusion pump,<sup>3059 3060 3062 3063 3064</sup> or intramuscular injection.<sup>3057</sup> The route of administration and, where applicable, the rate of infusion depend upon the product selected, the indication for the drug, and patient-specific risk factors.<sup>3053 3054 3055 3056 3057 3058 3059 3060 3061 3062 3063 3064 3065 3066 3067</sup>

For intravenous infusion, a slow initial infusion rate is usually maintained for 10 to 30 minutes prior to gradually (e.g., every 15 to 30 minutes) increasing the rate according to patient tolerance and the product-specific maximum rate.<sup>3053 3054 3055 3056 3059 3060 3061 3062 3065 3066 3067</sup>

For subcutaneous infusion, initial infusion rates range from 5 to 20 mL/hour per site, with product-specific maximum rates and number of infusion sites.<sup>3059 3060 3062 3063 3064 3240</sup> For subcutaneous infusion of HyQvia, a 24-gauge subcutaneous needle set that is labeled for high flow rates should be used.<sup>3064</sup>

GamaSTAN S/D is administered only by intramuscular injection; the drug should *not* be administered subcutaneously or intravenously.<sup>3057</sup>

## Stability

Recommended storage conditions vary among the different immune globulin human products.<sup>3075 3076</sup> Typically, intact immune globulin human products are stored either at room temperature, under refrigeration, or some combination of both and have a shelf life of about 24<sup>3055 3056 3058 3059 3061 3065 3066</sup> to 36 months<sup>3059 3060 3062 3067 3240</sup> from the date of manufacture.<sup>3075 3076</sup> Immune globulin human products should not be frozen.<sup>3053 3054 3055 3056 3057 3058 3059 3060 3061 3062 3063 3064 3065 3066 3067 3240</sup> Manufacturers of certain products state that the drug should be kept in the carton to protect from light.<sup>3055 3056 3059 3061 3063 3064 3067 3240</sup> Specific product labeling should be consulted for all storage requirements.

In general, liquid and reconstituted immune globulin human products should not be shaken.<sup>3053 3054 3058 3059 3060 3061 3062 3063 3064 3067 3240</sup>

Containers of immune globulin human are for single use only; partially used containers should be discarded.<sup>3053 3054 3055 3056 3057 3058 3059 3060 3061 3062 3063 3064 3065 3066 3067 3240</sup>

Most immune globulin human solutions are colorless to pale yellow in appearance.<sup>3053 3055 3056 3058 3059 3060 3061 3062 3064 3067 3240</sup> Oxidative reactions may be a cause of yellowish discoloration of intravenous immune globulin human solutions.<sup>3076</sup>

Two immune globulin human products (Gammagard S/D, Baxter and Polygam S/D [no longer commercially available in the US], American Red Cross) for intravenous use were reconstituted with sterile water for injection to concentrations of 50 mg/mL (5%) and 100 mg/mL (10%). Stability of the reconstituted product was evaluated in the original glass vials and also after transfer to PVC bags at 4°C for 48 hours and at 25°C for 12 hours. The visual appearance of the solutions remained acceptable, extremely low amounts of diethylhexyl phthalate (DEHP)

plasticizer were leached from the PVC bags, and all tests for protein content and antibody activity indicated that stability was maintained throughout the study under both storage conditions.<sup>2435</sup>

### pH Effects

One study evaluated multiple substances (e.g., sugars, polyalcohols, amino acids) for their ability to stabilize dissolved immune globulin G (IgG) molecules to prevent aggregation, dimerization, and fragmentation across a range of pH conditions when stored at 37°C for 90 days.<sup>3076</sup> The lowest percentage of aggregates was observed at weakly acidic conditions (pH 5.3) and the highest percentage of aggregates was observed at the lowest pH tested (i.e., 4.8 for L-lysine and L-ornithine; 4.1 for all other stabilizers tested).<sup>3076</sup> L-Proline, sucrose, and maltose showed good stabilizing effects over the entire pH range tested (4.1 to 6.8); glycine was less effective over this range, and L-lysine and L-ornithine were only marginally stabilizing at pH 6.8.<sup>3076</sup>

In terms of dimerization, L-proline was the most effective stabilizer tested, decreasing the percentage of dimers over the entire pH range tested.<sup>3076</sup> Sucrose also was effective over the entire pH range tested; however, its effects were less robust than those of L-proline.<sup>3076</sup> Glycine, L-lysine, and L-ornithine had negligible effects on dimerization, with glycine being the least effective.<sup>3076</sup> Mannitol and maltose actually increased dimer formation as compared with control solutions of immune globulin not containing a stabilizer.<sup>3076</sup>

The greatest amounts of fragmentation occurred at the lowest pH tested (i.e., 4.1).<sup>3076</sup> No substantial differences in fragmentation were observed among solutions containing L-proline, glycine, or no stabilizer except at a neutral pH of 6.8, where the formulation without stabilizer contained slightly more fragments.<sup>3076</sup> These results suggest that glycine and L-proline have

a small inhibitory effect on neutral proteases (e.g., serine proteases).<sup>3076</sup>

### Sorption

A stability evaluation of immune globulin human for intravenous use in PVC bags found no loss of activity due to sorption when compared to glass containers.<sup>2435</sup>

### Filtration

For details on filtration of immune globulin human products, the product labeling should be consulted; some manufacturers do not make specific recommendations.

Carimune NF (CSL Behring) may be filtered, but filtration is not required.<sup>3054</sup> Filters with pore sizes of 15 µm or larger will be less likely to slow the infusion, especially at higher concentrations.<sup>3054</sup> Antibacterial filters (i.e., 0.2-µm filters) may be used.<sup>3054</sup>

Use of an inline filter with Gammagard Liquid (Baxter) is optional.<sup>3059</sup>

The administration set provided with Gammagard S/D (Baxter) contains an integral airway and a 15-µm filter.<sup>3058</sup> If an alternative administration set is used to administer the drug, an administration set containing a similar filter should be used.<sup>3058</sup>

Inline filtration is not required with Octagam (Octapharma); however, if a filter is used, the pore size should be 0.2 to 200 µm.<sup>3065 3066</sup>

### Plasticizer Leaching

Storage of reconstituted immune globulin human for intravenous use in PVC containers for 48 hours at 4°C and 12 hours at 25°C resulted in very low amounts of leached DEHP plasticizer from undetectable amounts up to a maximum of 86 ng/mL.<sup>2435</sup>

## Compatibility Information

### Additional Compatibility Information

Immune globulin human products are manufactured using differing processes and exhibit differing compatibility and stability characteristics.<sup>3075</sup> All manufacturers recommend using a separate infusion line for administration and not mixing other drugs with immune globulin human.<sup>3053 3054 3055 3056 3058 3059 3060 3061 3062 3063 3064 3065 3066 3067 3240</sup> Pooling of vials of the same product and strength (and where applicable, the same diluent used for reconstitution) into sterile empty infusion containers is acceptable to facilitate the administration of large doses; however, storage requirements and the maximum duration of time allowed from the time of pooling to infusion vary among products.<sup>3053 3054 3055 3056 3058 3059 3060 3061 3062 3064 3065 3066 3067</sup> Specific product labeling should be consulted. Different formulations of immune globulin human from the same or different manufacturers should not be mixed.<sup>3053 3054 3055 3056 3058 3059 3060 3061 3062 3063 3064 3065 3066 3067</sup> The manufacturers make the recommendations cited in Table 4 regarding compatibility with infusion solutions.

**Table 4. Immune globulin human products: compatibility with infusion solutions**

Product	Remarks	Ref
Bivigam	Do not dilute.	3053
Carimune NF	May be reconstituted with sodium chloride 0.9%, dextrose 5%, or sterile water for injection.	3054
Cuvitru	Do not dilute.	3240
Flebogamma DIF	Do not dilute.	3055, 3056
Gammagard Liquid	May be diluted with dextrose 5%; incompatible for dilution with sodium chloride 0.9%. Line may be flushed with sodium chloride 0.9%.	3059
Gammagard S/D	Reconstitute with sterile water for injection packaged with drug.	3058

**Table 4. Immune globulin human products: compatibility with infusion solutions (Cont.)**

Product	Remarks	Ref
Gammaked	May be diluted with dextrose 5%; incompatible for dilution with sodium chloride 0.9%. Line may be flushed with either dextrose 5% or sodium chloride 0.9%.	3060
Gamunex-C	May be diluted with dextrose 5%; incompatible for dilution with sodium chloride 0.9%. Line may be flushed with either dextrose 5% or sodium chloride 0.9%.	3062
HyQvia	Line may be flushed with either sodium chloride 0.9% or dextrose 5%.	3064
Octagam	Do not dilute. Line may be flushed with sodium chloride 0.9% or dextrose 5%.	3065, 3066
Privigen	May be diluted with dextrose 5%. Line may be flushed with dextrose 5% or sodium chloride 0.9%.	3067

**Heparin Locks**

The manufacturer of Gammaked and Gamunex-C immune globulin human products (Grifols) specifically states that heparin locks through which either drug has been administered should be flushed only with dextrose 5% or sodium chloride 0.9%; heparin should *not* be used to flush the lock.<sup>3060 3062</sup>

AHFS 28:08.04.92

### Products

Indomethacin sodium trihydrate is supplied as a lyophilized product in vials containing the equivalent of 1 mg of indomethacin. Reconstitute with 1 or 2 mL of preservative-free sterile water for injection or sodium chloride 0.9% to yield a 1- or 0.5-mg/mL solution, respectively.<sup>1(7/06)</sup>

### pH

From 6 to 7.5.<sup>4</sup>

### Trade Name(s)

Indocin I.V.

### Administration

Indomethacin sodium trihydrate is usually administered by intravenous injection over 20 to 30 minutes, although dilution after reconstitution is not recommended. Extravasation should be avoided.<sup>1(7/06)</sup> <sup>4</sup>

### Stability

Indomethacin sodium trihydrate is supplied as a white to yellow powder. Color variations have no relationship to indomethacin content. The vials should be stored below 30°C and protected from light.<sup>1(7/06)</sup>

The manufacturer recommends discarding any unused solution because of the absence of an antibacterial preservative.<sup>1(7/06)</sup> However, at 1 mg/mL in sodium chloride 0.9%, the drug is stated to be chemically stable for 16 days at room temperature.<sup>4</sup>

Solutions of indomethacin sodium trihydrate (Abbott and Fujisawa) diluted in sodium chloride 0.9% to a concentration of 0.1 mg/mL were evaluated for visual and chemical stability stored in the original vials. Little or no loss was found after storage for 10 days at 25°C.<sup>2105</sup>

The stability of indomethacin sodium trihydrate (Merck Sharp & Dohme) 0.5 mg/mL reconstituted with sterile water for injection in the original vials and repackaged into 1-mL polypropylene syringes (Sherwood) was reported. The reconstituted solutions were stored at room temperature (about 23°C) exposed to fluorescent light for 12 hours daily and under refrigeration (about 4°C) in the dark. Little or no loss of indomethacin in the refrigerated solutions occurred after 14 days of storage. The solutions stored at room temperature exhibited 9% loss in 10 days. The solutions at both temperatures remained visually clear and colorless throughout the study.<sup>2228</sup>

### pH Effects

Reconstitution of indomethacin sodium trihydrate with solutions having pH values below 6 may result in precipitation of free indomethacin.<sup>1(7/06)</sup> <sup>4</sup>

# Infliximab

## AHFS 92:36

### Products

Infliximab is available as a lyophilized powder in 100-mg preservative-free, single-use vials.<sup>3035</sup> Each vial also contains sucrose 500 mg, polysorbate 80 0.5 mg, monobasic sodium phosphate monohydrate 2.2 mg, and dibasic sodium phosphate dihydrate 6.1 mg.<sup>3035</sup>

Calculate the required number of infliximab vials and the total volume of reconstituted solution needed to provide the appropriate dose.<sup>3035</sup> Each 100-mg vial should be reconstituted by transferring 10 mL of sterile water for injection into the vial using a syringe with 21-gauge or smaller needle, directing the stream of diluent against the vial wall.<sup>3035</sup> The solution should be gently swirled by rotating the vial to dissolve the powder.<sup>3035</sup> Foaming of the solution may occur; the reconstituted solution should be allowed to stand for 5 minutes.<sup>3035</sup> Prolonged or vigorous agitation should be avoided; the vial should *not* be shaken.<sup>3035</sup> The resultant reconstituted solution contains infliximab 10 mg/mL.<sup>3035</sup>

The total volume required of the reconstituted infliximab solution should be further diluted to 250 mL by first removing a volume of diluent (equal to the volume of infliximab solution to be added) from a 250-mL container of sodium chloride 0.9%.<sup>3035</sup> The appropriate dose of the reconstituted solution should then be slowly added to the bottle or bag and gently mixed.<sup>3035</sup> The manufacturer states that solutions other than 0.9% sodium chloride should *not* be used for dilution.<sup>3035</sup> The final concentration of infliximab in the resultant diluted solution should be between 0.4 and 4 mg/mL.<sup>3035</sup>

### pH

Reconstituted infliximab solutions have a pH of approximately 7.2.<sup>3035</sup>

### Trade Name(s)

Remicade

### Administration

Infliximab is administered by intravenous infusion over a period of at least 2 hours.<sup>3035</sup> The diluted solution for infusion *must* be administered through an infusion set with a low-protein-binding inline filter with a pore size of 1.2 µm or smaller.<sup>3035</sup>

### Stability

Intact vials of infliximab should be stored at 2 to 8°C.<sup>3035</sup> These unopened vials also may be stored at temperatures not exceeding 30°C with up to 75% relative humidity for a single period of up to 6 months; however, the cartons of such vials must be marked with a new expiration date of 6 months after transfer to these storage conditions.<sup>3035 3077</sup> Vials should be used by the newly marked expiration date or the original expiration date printed on the carton, whichever comes first.<sup>3035 3077</sup> The

drug should not be returned to refrigerated storage once it has been removed.<sup>3035 3077</sup>

Results of a stability study of unreconstituted infliximab vials stored at -20°C for 7 days with 3 freeze-thaw cycles followed by storage for up to 28 months at 2 to 8°C did not demonstrate any adverse effects on the biochemical or physical properties of infliximab.<sup>3077</sup> No adverse effects on the biochemical and physical properties of infliximab were observed following exposure of vials of the unreconstituted drug to 50°C for 3 days and return to the recommended temperature range of 2 to 8°C for 28 months; no significant increase in visible particle content was observed following exposure to 50°C for 3 days or at the 28-month time point after exposure.<sup>3077</sup>

Infliximab is a white lyophilized powder that forms an opalescent, colorless to light yellow solution when reconstituted with sterile water for injection.<sup>3035</sup> The solution may develop a few translucent particles because infliximab is a protein.<sup>3035</sup> The drug should be visually inspected for discoloration and particulate matter prior to administration.<sup>3035</sup> The solution should not be used if the lyophilized cake has not fully dissolved or if visibly opaque particles, foreign particles, or discoloration is present.<sup>3035</sup>

The manufacturer states that administration of the drug should begin within 3 hours of reconstitution and dilution to protect against microbiological contamination.<sup>3035 3079</sup>

In studies evaluating the stability of infliximab after reconstitution, the drug was found to remain biochemically and physically stable for 24 hours at room temperature when reconstituted with sterile water for injection, sodium chloride 0.45%, or sodium chloride 0.9%.<sup>3078 3080</sup> Reconstitution of the drug with dextrose 5% resulted in an irreversible reaction detected within 24 hours by changes in the isoelectric focusing banding pattern as compared with the reference standard; reconstitution of the drug with dextrose 5% is not recommended.<sup>3078</sup>

Ikeda et al. studied the stability of infliximab at a concentration of 0.4 mg/mL in sodium chloride 0.9% in PVC bags, which were stored at 4°C for up to 14 days.<sup>3122</sup> An indirect ELISA method was used to determine infliximab activity based on calculated consumption of a known quantity of tumor necrosis factor [TNF; TNF-α] when combined with infliximab.<sup>3122</sup> The authors reported that no loss of infliximab's ability to bind TNF-α was detected at 7 or 14 days.<sup>3122</sup> However, other measures of stability (e.g., physical or chemical analyses or other bioassay results) were not reported in this study;<sup>2812 3122</sup> in addition, the manufacturer stated that the protocols and methods it has used to assess infliximab stability are proprietary and specific to the drug, and it cannot support nor refute the results of this study.<sup>2290</sup>

### Plasticizer Leaching

The surfactant (polysorbate 80) contained in the infliximab formulation can leach plasticizer from diethylhexyl phthalate

(DEHP)-plasticized PVC containers and administration sets.<sup>3035</sup>

<sup>3081</sup> To eliminate the potential for exposure to DEHP for patients receiving infliximab, the use of DEHP-containing PVC equipment with infliximab was previously restricted; however, potential exposure to DEHP from a dose of infliximab (for a 50- to 70-kg patient) was found to be approximately 50 to 70 times lower than the reference dose for DEHP set by the US Environmental Protection Agency (EPA) based on results of DEHP

toxicity studies.<sup>3081</sup> Based on this information, the requirement of using non-PVC administration equipment with infliximab has been removed from the current prescribing information.<sup>3035 3081</sup>

### Filtration

The diluted solution of infliximab for infusion *must* be administered with an infusion set containing a low-protein-binding inline filter with a pore size of 1.2 µm or smaller.<sup>3035</sup>

## Compatibility Information

## Insulin

AHFS 68:20.08

### Products

Regular insulin is available in 10-mL vials and 1.5-mL prefilled syringes and syringe cartridges at a concentration of 100 units/mL. Human insulin is produced using recombinant DNA technology. Regular concentrated insulin (Lilly) also is available in 20-mL vials containing 500 units/mL. Glycerin 1.4 to 1.8% and phenol or cresol 0.1 to 0.25% also may be present.<sup>1(1/08) 4</sup>

Several modified forms of insulin (Isophane, Lente, etc.) are available, each having a characteristic onset of action, time to peak effect, and duration of action.<sup>4</sup>

Adequately mixing these products is necessary prior to use, but vigorous shaking may entrain air bubbles that could interfere with accurate dosing. Gentle shaking of the vial combined with end-over-end inversion and rolling in the palms has been suggested.<sup>2270</sup>

### pH

All regular insulin products have a neutral pH of approximately 7 to 7.8.<sup>4 261</sup>

### Trade Name(s)

Humulin R

### Administration

Regular insulin usually is administered by subcutaneous injection into the thighs, arms, buttocks, or abdomen, with sites rotated. Syringes calibrated for the particular concentration of insulin to be given must be used. Regular insulin also may be administered intramuscularly or by intravenous infusion, usually diluted in sodium chloride 0.9%. Regular insulin is the only form of insulin that can be given intravenously.<sup>4</sup>

Care is required when adding insulin to infusion solutions, especially in flexible containers. Adding insulin to a plasma expander carrier solution hanging in the use position resulted in stratification, with the insulin floating to the top. Little insulin was delivered initially, and 87% of the insulin appeared in the last 28% of the solution. Repeated inversion and agitation of the container to effect thorough mixture eliminates this stratification, yielding an even distribution and a constant delivery concentration.<sup>85</sup>

Disposable insulin syringes are usually siliconized. Reuse of disposable plastic insulin syringes (Plastipak Microfine II, Becton Dickinson) has resulted in contamination of vials of insulin with silicone oil, causing a white precipitate and impairment of biological effects and is not recommended. In a test of insulin from several sources, repeated drawing of the insulin into the disposable syringes and then expulsion of it back into the vials introduced substantial amounts of silicone oil; a white precipitate formed within 12 hours at 8°C.<sup>1110</sup>

### Stability

Regular insulin should be stored under refrigeration and protected from freezing.<sup>1(1/08) 4</sup> Although refrigerated storage is required, some manufacturers have stated the drug may be stored at room temperature for 28 to 30 days.<sup>2745 2769</sup> Freezing of insulin products may alter the protein structure, decreasing concentration.<sup>559</sup> In one study of several insulin products, 1 cycle of freezing for 45 hours followed by slow thawing at 21°C or rapid thawing in a water bath at 37°C did not result in a loss of bioactivity. However, microscopic examination revealed particle aggregation, and some crystal damage had occurred.<sup>680</sup>

The stability of regular insulin (Novo Nordisk) was evaluated under simulated shipping conditions. Sample vials were packaged in both insulated and non-insulated mailers and packaged with either two 12-oz. frozen gel packs for simulated summer mailing or one 12-oz. frozen gel pack for simulated winter shipping. The evaluation was conducted for simulated transit periods ranging from 24 hours to 120 hours (overnight air delivery to ground delivery). Visual inspection found no change in appearance in any of the samples tested. Microscopy found no formation of aggregates. No loss of insulin content occurred in any of the samples with any of the shipping methods and conditions. Size exclusion chromatography found little or no change in high-molecular-weight protein content. The regular insulin remained within USP specifications with all of the shipping methods and time periods studied.<sup>2769</sup>

As with other protein and peptide products, insulin aggregation with possible reduced bioactivity can be a problem. Aggregates have been found to form in a variety of infusion devices and under various storage conditions, including static storage and continuous rotational or reciprocating motion.<sup>1948 1995 2406</sup> Aggregation may occur at air-water interfaces. Such interfaces have been generated by turbulence, such as shaking and repeatedly passing insulin through a syringe and needle. With sufficient vigor, both actions can turn the insulin turbid from insoluble aggregates.<sup>1948</sup> In addition, contact with silicone rubber appears to promote insulin aggregation.<sup>1995</sup>

Factors that increase the formation rate of insulin transformation products (such as deamidated insulin, covalent dimers, and higher oligomers) in beef and human insulin products were evaluated during 6 months of storage. A low rate of transformation product appeared at 4°C. Higher temperatures, as might occur when insulin is carried in a shirt pocket or car glove compartment, accelerated this production (especially for human insulin) and also fibril formation. Exposure to light increased the dimer and higher oligamer content. Insulin should not be exposed to direct sunlight or subjected to vibration or extremes of temperature.<sup>1663</sup>

The appearance of transformation products was found to be 2- to 3-fold greater when using polyvinyl chloride (PVC) administration sets compared to polyethylene and polypropylene infusion equipment. Furthermore, use of the PVC sets resulted in up to 30% reduction in the concentration of methylparaben, phenol, and m-cresol preservatives in insulin products.<sup>311</sup>

Regular insulin, containing 100 units/mL, is clear and colorless or almost colorless. The concentrated injection containing 500 units/mL may be straw colored. Discoloration, turbidity, or unusual viscosity indicates deterioration or contamination.<sup>4</sup>

### Syringes

It has been stated that neutral regular insulin (and also NPH and Lente insulin) can be stored for 5 to 7 days under refrigeration in either glass or plastic syringes. Mixtures of these insulins also can be stored similarly.<sup>679</sup>

Insulin soluble, BP, 1.6 units/2 mL diluted in sodium chloride 0.9% was stored for 18 hours at room temperature in the following plastic syringes: Brunswick (Sherwood Medical), Plastipak (Becton Dickinson), and Sabre (Gillette U.K.). The first 2 syringes have polypropylene barrels; the Sabre has a combination polypropylene–polystyrene barrel. No significant loss of insulin occurred due to sorption. Significant (but unspecified) losses did occur when the concentration was reduced to 0.2 unit/mL, but the make of syringe did not influence this adsorption.<sup>784</sup>

No apparent degradation or binding occurred for at least 14 days when insulin, USP (Lilly), 100 units/mL was stored under refrigeration in 1-mL polypropylene syringes (Becton Dickinson).<sup>805</sup>

The soluble insulins Velosulin (Nordisk), Actrapid and Human Actrapid (Novo), Humulin S (Lilly), Neusulin (Wellcome), and Quicksol (Boots) in 1-mL 100-unit Plastipak syringes (Becton Dickinson) exhibited no loss in 29 days when stored at 4 and 20°C.<sup>1275</sup>

Regular insulin human (Humulin R, 100 units/mL, Lilly), isophane insulin human (Humulin N, 100 units/mL, Lilly), and the combination product (Humulin N/R 70/30, Lilly) were evaluated for stability packaged in plastic syringes. Test samples of 0.4 mL of each insulin product were drawn into 1-mL polypropylene syringes (Plastipak, Becton Dickinson) and 1-mL polypropylene–ethylene copolymer syringes (Terumo) and stored for 28 days at 4 and 23°C. No loss of insulin from any insulin product occurred in either syringe type. However, the antibacterial preservatives present in the insulin formulations were lost, especially in the polypropylene syringes at room temperature. Storage under refrigeration to slow the loss of preservative as much as possible was recommended.<sup>1124</sup>

### Infusion Pumps

Insulin solutions may form highly insoluble polymers. In areas having high shear rates such as the tubing, cannula, and needle, aggregation can lead to blockage. In low shear areas such as the insulin reservoir of implantable pumps, gentle agitation can lead to the formation of a cross-linked gel.<sup>1112</sup>

### Sorption

The adsorption of insulin to the surfaces of intravenous infusion solution containers, glass and plastic (including PVC, ethylene

vinyl acetate [EVA], polyethylene, and other polyolefins), tubing, and filters has been demonstrated. Estimates of the loss range up to about 80% for the entire infusion apparatus, although varying results using differing test methods, equipment, and procedures have been reported. Estimates of adsorption of around 20 to 30% are common. The percent adsorbed is inversely proportional to the concentration of insulin. Other important factors are the amount of container surface area and the fill volume of the solution. The amount of insulin adsorbed varies directly with the available surface area and indirectly with the ratio of fluid volume to container capacity. The container material is a factor, with glass possibly adsorbing insulin more extensively than some plastics. Other factors influencing the extent of insulin adsorption include the type of solution, type and length of administration set, rate of infusion, temperature, previous exposure of tubing to insulin, and presence of albumin human, whole blood, electrolytes, and other drugs.<sup>266 267 268 269</sup>

420 422 423 424 425 426 428 533 681 682 683 684 685 686 687 688 689 690 854 908 909 910  
911 912 913 1111 1112 1274 1282 1408 1497 1664 1665 2079 2301

The adsorption of insulin to container surfaces is an instantaneous process.<sup>267 425 911 912 913</sup> However, the effect of adsorption on the deliverable amount of insulin appears to vary with time. Several investigators reported a dramatic initial drop in delivered insulin followed by a return to higher (although variable) levels. The bulk of the insulin adsorption apparently occurs in the first 30 to 60 minutes. Although flow rate does not influence total insulin binding, the plateau phase of delivered insulin may be reached more quickly at faster infusion rates.<sup>422 424 425 426</sup>

428 687 688 689 854 2301

In a study of insulin loss during simulated delivery to low-birth-weight infants, insulin 0.2 unit/mL was delivered at rates of 0.05 and 0.2 mL/hr through microbore PVC tubing and polyethylene-lined PVC tubing. During the early hours, the amount of insulin delivered through both types of tubing was much reduced, especially at the slower delivery rate. The authors indicated that this loss might contribute to the 14- to 24-hour delays in blood glucose normalization in these infants. The priming of microbore tubing with 5 units/mL of insulin for 20 minutes was suggested to accelerate the achievement of steady-state insulin delivery. The time courses of insulin delivery observed for representative unprimed and primed sets are presented in Table 1.<sup>2301</sup>

Regular human insulin 0.1 unit/mL in sodium chloride 0.9% in VISIV polyolefin bags was tested for 24 hours at room temperature near 23°C. About 35% loss occurred, which is consistent with the drug's potential for adsorption to surfaces.<sup>2660 2792</sup>

**Table 1. Approximate amount of insulin delivered through unprimed and primed<sup>a</sup> administration sets<sup>2301</sup>**

Set Type	Delivered Insulin (%)				
	1 hr	2 hr	4 hr	8 hr	24 hr
Unprimed	17	11	27	55	100
Primed	70	70	70	100	100

<sup>a</sup> Primed with insulin 5 units/mL for 20 minutes.

The addition of albumin human to infusion solutions helps to reduce the adsorption of insulin. The degree to which albumin human prevents adsorption is uncertain. Reported losses of insulin in albumin-containing solutions have varied from about zero to approximately 30%. However, most work indicates a substantial reduction in insulin adsorption.<sup>266 267 268 269 418 428 683 684 685 908 909</sup> Other additives such as vitamins, electrolytes, and drugs may also have a similar effect.<sup>425 909 914</sup>

Other recommended approaches to avoiding or minimizing adsorption include adding a small amount of the patient's blood to the insulin solution<sup>689 690 691</sup> and storing or flushing the administration apparatus with the insulin solution to saturate the set prior to administration.<sup>428 1111 2301</sup> Addition of extra insulin to compensate for the losses has also been suggested.<sup>1112</sup> As an alternative, administration of insulin using a syringe pump with a short cannula has been recommended. This procedure will reduce the surface area in relation to the amount of insulin present.<sup>1033</sup>

The clinical significance of this adsorption is uncertain. Some clinical studies indicated no relevant effect on the success of therapy.<sup>415 427 685</sup> Some investigators felt that the importance of insulin adsorption to the surfaces of the infusion container and tubing may be a moot point since the dosage is individualized on the basis of blood and urine glucose determinations. Simply adding more insulin may saturate binding sites and yield the desired response.<sup>270 271 854 909</sup>

Still others indicated that the adsorption may indeed be relevant for solutions with an insulin content of less than 100 or 200 units/L.<sup>424 426 428 908 2301</sup>

If the apparent dose of intravenous insulin is used as the basis for determining the subsequent dose upon discontinuing the intravenous one, then a potential for dosing error exists. The actual amount of insulin being administered could be substantially less than the apparent amount.<sup>533</sup>

Whether one attempts to prevent insulin adsorption or not, it does not appear to be possible to add an amount of insulin to an infusion solution and know precisely what portion of that amount will actually be given to the patient. Monitoring the patient's response to therapy and making the appropriate adjustments on the basis of that response are, therefore, of prime importance.<sup>690 854 1664</sup>

### Implantable Pumps

Insulin, regular human (Genapol, Hoechst-Roussel) 400 units/mL with heparin sodium 500 units/mL was evaluated in MIP 2001 implantable pumps (MiniMed) at 37°C for 3 months. The drug solution remained visually clear, but the insulin content dropped to 65% of the initial amount. The activity of heparin declined by even more. Only 45% remained after 3 months. The losses were attributed to the shaking that occurred during use rather than temperature, interaction with pump materials, or interaction of the 2 drugs with each other.<sup>239</sup>

## Compatibility Information

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>d</sup> Tested in sodium chloride 0.45%.

<sup>e</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>f</sup> Tested in dextrose 5%, sodium chloride 0.9%, and Ringer's injection, lactated.

<sup>g</sup> Tested in Ringer's injection, lactated.

<sup>h</sup> Tested in sterile water for injection.

<sup>i</sup> Tested in dextrose 5% in Ringer's injection, lactated.

<sup>j</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>k</sup> Tested in Haemaccel (Behring).

<sup>l</sup> Ampicillin component. Ampicillin in a 2:1 fixed-ratio concentration with sulbactam.

<sup>m</sup> Not specified whether concentration refers to single component or combined components.

<sup>n</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>o</sup> Quinupristin and dalbapristin components combined.

<sup>p</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>q</sup> Test performed using the formulation WITH edetate disodium.

## Additional Compatibility Information

### Mixing Insulin Products

Mixing of the various types of insulin has been utilized. The following compatibility results have been cited:<sup>1076</sup>

Insulin Types	Compatibility
Regular with NPH	Mixtures are stable in all ratios
Regular with protamine zinc	Stability is unpredictable
Regular with Lente	Reduces activity of regular due to binding to excess zinc
Lente, Semilente, Ultralente	Mixtures are stable in all ratios
Lente, Semilente, Ultralente with phosphate-buffered insulins <sup>a</sup>	Should not be mixed due to precipitation

<sup>a</sup> Includes Humulin BR, NPH, protamine zinc, Velosulin insulins.

It has been stated that neutral regular insulin may be combined with modified insulin in any proportions.<sup>263 264</sup> However, losses of soluble insulins when mixed with zinc and isophane insulins were reported. These losses generally ranged from about 20 to 50% but were as high as 99%, depending on the ratio and sources of the 2 insulins in the mixture. The reaction occurred within the first 90 to 120 seconds after mixing, with no further losses occurring after this time. This phenomenon could explain clinical reports of failure to control postprandial blood sugar levels.<sup>1275</sup>

The loss of solubility when short-acting insulins were mixed in ratios of 1:1, 1:2, 1:3, and 1:5 with long-acting insulins was reported. Iletin II Regular (Lilly) was mixed with Iletin II Lente, NPH, or Ultralente (Lilly). Actrapid (Novo) was mixed with Monotard (Novo). Velosulin (Nordisk) was mixed with Insulatard (Nordisk). The mixtures were centrifuged after storage times of approximately 20 minutes and 75 seconds. The level of soluble short-acting insulin in the supernatant was determined. In a 1:1 ratio, no significant loss of solubility occurred with the Iletin II Lente combination within 20 minutes and with the Actrapid–Monotard combination in 75 seconds. All other combinations, ratios, and time periods had losses ranging from 10 to 75%. The worst losses were experienced with the highest ratios of long-acting insulins and with the longer time period. The method used to prolong insulin action (precipitation) might affect the solubility of the short-acting insulin when admixed.<sup>1156</sup>

The loss of initial hypoglycemic effect when Actrapid HM (Novo) was mixed with Ultratard HM (Novo), an ultralente insulin, for 5 minutes before injection was noted. The authors recommended not mixing the 2 types of insulin to preserve the rapid hypoglycemic effect of regular insulin.<sup>73</sup>

### Octreotide

Insulin levels in a 3-L bag of parenteral nutrition solution showed a marked reduction when octreotide 150 mcg was added to the container. Sample parenteral nutrition solutions, with and without octreotide, were prepared with regular insulin 15 units/3-L bag. Subsequent analysis found an insulin level of 3.5 units/L in the plain parenteral nutrition solution, an amount

consistent with the losses occurring due to surface adsorption. However, in the parenteral nutrition solution containing octreotide, the insulin level was only 0.6 unit/L. The reason for this potential incompatibility is not known.<sup>1377</sup>

### ***Peritoneal Dialysis Solutions***

Insulin 4, 10, 20, and 40 units/L was evaluated in the following Baxter peritoneal dialysis solutions in PVC and Clear-Flex polyolefin containers:

- Dianeal PD-4 with 1.36% dextrose in PVC containers
- Physioneal 40 with 1.36% dextrose in PVC containers
- Physioneal 40 Clear-Flex with 1.36% dextrose in Clear-Flex

In Dianeal PD-4, more than 90% of the insulin concentration remained over 24 hours. The insulin 10, 20, and 40 units/L in Physioneal 40 retained more than 90% of the insulin concentration over 6 hours and more than 80% over 24 hours. The insulin 4 units/L in Physioneal 40 retained more than 90% of the insulin concentration over 3 hours and more than 70% over 24 hours. No difference was found between the results in PVC and Clear-Flex containers.<sup>2647</sup>

## Insulin Lispro

AHFS 68:20.08

### Products

Insulin lispro is available in vials, cartridges, and pens as a suspension containing in each mL insulin lispro 100 units with glycerin 16 mg, dibasic sodium phosphate 1.88 mg, metacresol 3.15 mg, zinc ion 0.0197 mg (as oxide), a trace of phenol, and sodium hydroxide and/or hydrochloric acid to adjust pH during manufacturing in water for injection.<sup>1(9/07)</sup>

### pH

From 7.0 to 7.8.<sup>1(9/07)</sup>

### Trade Name(s)

Humalog

### Administration

Insulin lispro is an injectable suspension intended for subcutaneous injection including using some external insulin pumps.<sup>1(9/07)</sup>

### Stability

Intact vials of insulin lispro should be stored under refrigeration and protected from freezing, excessive heat, and light.<sup>1(9/07)</sup>

Although refrigerated storage is required, the manufacturer has stated the drug may be stored at room temperature for 28 days. Visually inspect insulin lispro before use. Discard if it is cloudy, contains a precipitate, has thickened, or is discolored.<sup>1(9/07) 2745</sup>

Insulin lispro diluted with Sterile Diluent for Humalog to 10 or 50 units/mL can be used for 28 days refrigerated and for 14 days at room temperatures up to 30°C. If diluting insulin lispro, great care is essential to avoid concentration errors. Insulin lispro in a cartridge or used in an external insulin pump must not be diluted.<sup>1(9/07)</sup>

Insulin lispro cartridges used in D-TRON and D-TRON Plus external pumps should be discarded after seven days and the cartridge adapters and external pump reservoir should be discarded every 48 hours.<sup>1(9/07)</sup>

The physical and chemical stability of insulin lispro 100 units/mL in MiniMed507c, H-TRONplus, and D-TRON CSII insulin infusion devices stored at 37°C and subjected to mechanical shaking at 100 strokes/min was evaluated over 7 days. The insulin lispro solution remained clear and free of aggregation and precipitation, and concentrations remained at 95%.<sup>2638</sup>

## Interferon Alfa-2b

AHFS 8:18.20

### Products

Interferon alfa-2b is available as a dry powder for injection in single-use vials containing 10, 18, or 50 million international units packaged with sterile water for injection diluent.<sup>2952</sup>

Select the vial size and dosage form that are appropriate for the intended use of the product.<sup>2952</sup> Only the 10-million international unit dry powder for injection single-use vial is recommended for intralesional use.<sup>2952</sup> The 50-million international unit dry powder for injection single-use vial is used only in the treatment of malignant melanoma or AIDS-related Kaposi's sarcoma.<sup>2952</sup>

For *intramuscular, subcutaneous, or intralesional* use, reconstitute the 10-, 18-, or 50-million international unit dry powder for injection vials with 1 mL of the provided sterile water for injection diluent to yield solutions containing 10, 18, or 50 million international units/mL, respectively.<sup>2952</sup> Direct the stream of diluent at the vial wall.<sup>2953</sup> Gently swirl in a circular motion to dissolve the powder;<sup>2952</sup> do not shake.<sup>2953</sup> If undissolved powder remains, gently invert the vial until the remainder of the powder is dissolved.<sup>2953</sup>

In addition to the drug, each mL of the reconstituted solutions contains glycine 20 mg, sodium phosphate dibasic 2.3 mg, sodium phosphate monobasic 0.55 mg, and albumin human 1 mg.<sup>2952</sup> These vials contain no preservative.<sup>2952</sup>

For *intravenous infusion*, reconstitute the appropriately sized dry powder for injection vial contents with the diluent provided.<sup>2952</sup> Gently swirl to dissolve the powder;<sup>2952</sup> do not shake.<sup>2953</sup> If undissolved powder remains, gently invert the vial until the remainder of the powder is dissolved.<sup>2953</sup> Withdraw the appropriate dose and add it to 100 mL of sodium chloride 0.9%, ensuring that the final concentration is not less than 10 million international units/100 mL.<sup>2952</sup>

Interferon alfa-2b also is available as a solution for intramuscular, subcutaneous, or intralesional use in multidose vials labeled as containing 18 million international units (22.8 million international units/3.8 mL [i.e., 6 million international units/mL]) or 25 million international units (32 million international units/3.2 mL [i.e., 10 million international units/mL]).<sup>2952</sup> Only the 25-million international unit (32-million international units/3.2 mL [i.e., 10-million international unit/mL]) solution is recommended for intralesional use.<sup>2952</sup> Each mL of solution also contains sodium chloride 7.5 mg, sodium phosphate dibasic 1.8 mg, sodium phosphate monobasic 1.3 mg, edetate disodium 0.1 mg, polysorbate 80 0.1 mg, and metacresol 1.5 mg.<sup>2952</sup> The solution products are albumin-free.<sup>2952</sup>

Interferon alfa-2b solution products are not labeled for intravenous administration.<sup>2952</sup>

### Specific Activity

Approximately  $2.6 \times 10^8$  international units/mg of protein.<sup>2952</sup>

### Tonicity

Reconstitution of the 10-million international unit vial with 1 mL of water for injection results in an isotonic solution.<sup>1369</sup>

### Trade Name(s)

Intron A

### Administration

The administration of interferon alfa-2b is dependent upon the intended use and specific dosage form.<sup>2952</sup> The dry powder products, reconstituted as directed, may be administered by intramuscular and subcutaneous injection or intravenous infusion.<sup>2952</sup> The contents of the 10-million international unit vial, reconstituted as directed, also may be given by intralesional injection.<sup>2952</sup> For intravenous infusions, interferon alfa-2b may be diluted further to a concentration of not less than 10 million international units/100 mL of sodium chloride 0.9% to be infused over 20 minutes.<sup>2952</sup>

The solution products are administered by intramuscular or subcutaneous injection.<sup>2952</sup> The labeled 25-million international unit multidose vial also may be used for intralesional injection.<sup>2952</sup> The solution products are *not* for use in the treatment of malignant melanoma or AIDS-related Kaposi's sarcoma.<sup>2952</sup>

### Stability

Interferon alfa-2b dry powder in vials is a white to cream color.<sup>2952</sup> It is not photosensitive.<sup>1369</sup> The reconstituted solution is clear and colorless to light yellow.<sup>2952</sup> Intact vials should be stored under refrigeration at 2 to 8°C,<sup>2952</sup> but have been noted to be stable for up to 28 days at room temperature.<sup>1369</sup> The manufacturer recommends that the reconstituted solution be used immediately, but the solution may be stored under refrigeration for up to 24 hours.<sup>2952</sup>

Interferon alfa-2b solution in multidose vials is clear and colorless.<sup>2952</sup> Intact vials of solution should be stored under refrigeration at 2 to 8°C,<sup>2952</sup> but have been noted to be stable for up to 7 days at or below 25°C.<sup>2961</sup> After opening, vials have been found to be stable for up to 28 days at 2 to 8°C.<sup>2961</sup>

Interferon alfa-2b contains amino acid residues that are susceptible to oxidation.<sup>2961</sup> Although oxidation products might not directly affect cytokine activity, oxidized interferon alfa-2b is prone to aggregation; oxidation catalyzed by metals, in particular, may result in the formation of highly immunogenic aggregates.<sup>2961</sup> Therefore, edetate disodium has been included as a chelating agent in the solution formulation of interferon alfa-2b.<sup>2961</sup>

Interferon alfa-2b (Schering) containing albumin human in the formulation reconstituted with bacteriostatic water for injection and diluted further to 2 million international units/mL with sterile water for injection was stored at 4°C for 21 days in polypropylene centrifuge tubes. Biological activity was retained throughout the study period.<sup>2022</sup>

In another study, the retention of bioactivity by albumin-free interferon alfa-2b 6 million units/mL was compared to samples of that product to which albumin human 1 mg/mL was added and also to the reconstituted product containing albumin human in the formulation. The solutions were packaged as 0.5 mL in polypropylene syringes and stored at 4°C for 42 days. In addition, the albumin-free product was diluted to 2 million units/mL with sterile water for injection and stored in a 60-mL polypropylene syringe under the same conditions. No substantial loss of biological activity was found in any of the samples.<sup>2188</sup>

Sodium chloride 0.9% is recommended for preparation of intravenous infusion admixtures.<sup>2952</sup>

Interferon alfa-2b dry powder is stated to be compatible with sodium chloride 0.9%, Ringer's injection, and Ringer's injection, lactated.<sup>1369</sup> It is stated to be incompatible with dextrose solutions.<sup>1369</sup>

### **pH Effects**

Interferon alfa-2b is most stable between pH 6.9 and 7.5.<sup>1369</sup>

### **Freezing Solutions**

Interferon alfa-2b solutions frozen at -20°C are stated to be stable for 56 days including 4 freeze-thaw cycles.<sup>1369</sup> Frozen solutions stored at -80°C are stable for 1 year.<sup>1369</sup>

### **Syringes**

Interferon alfa-2b (Intron A, Kirby-Warwick) 3 million units was diluted in 6 mL of sterile water for injection and packaged in 10-mL polypropylene syringes. The samples were stored for 14 days under refrigeration and for 24 hours at 37°C. Analysis found changes indicating interconversion between interferon monomers and possibly oligomer formation. Dilution and packaging in polypropylene syringes was considered to be unsuitable.<sup>744</sup>

### **Sorption**

In general, cytokines are commonly susceptible to adsorption.<sup>2961</sup> Polysorbate 80, incorporated into interferon alfa-2b solution products, inhibits adsorption by competing with proteins for hydrophobic surfaces and interfaces.<sup>2961</sup> The solution dosage forms are albumin-free.<sup>2952</sup> Conversely, albumin human is incorporated into the dry powder dosage forms to minimize adsorption by competing with proteins for surface adsorption sites.<sup>2961</sup>

AHFS 36:68

### Products

Iodipamide meglumine is available in 20-mL vials containing an aqueous solution composed of 52% iodipamide meglumine (5.2 g bound iodine/20 mL) with 0.32% sodium citrate buffer and 0.04% edetate disodium.<sup>1(7/06) 4</sup>

### pH

From 6.5 to 7.7.<sup>1(7/06) 4</sup>

### Sodium Content

The 52% solution contains approximately 18.2 mg of sodium per 20 mL.<sup>1(7/06)</sup>

### Trade Name(s)

Cholografin Meglumine

### Administration

Iodipamide meglumine is administered slowly intravenously only. After warming to body temperature, the 52% injection is injected over 10 minutes.<sup>1(7/06) 4</sup>

### Stability

The solutions may vary from colorless to pale yellow or light amber. Darker solutions should not be used. Crystallization may occur in the 52% solution. To redissolve it, place the vial in hot water and shake gently for several minutes. If cloudiness does not disappear, the solution should not be used.<sup>1(7/06) 4</sup>

Plastic syringes have been stated to be unsuitable for accommodating radiopaque solutions for any length of time. The plastic is attacked, and the plunger tends to freeze on prolonged storage.<sup>40</sup> However, when iodipamide meglumine (Squibb) 52% was stored in polystyrene syringes (Pharmaseal) at 25 and 37°C, no apparent changes were noted visually or spectrophotometrically over five days.<sup>530</sup>

Iodipamide meglumine solutions should be protected from light and excessive heat.<sup>1(7/06)</sup>

## Iodixanol

AHFS 36:68

### Products

Iodixanol is available at 270 mg/mL of organically bound iodine (as 550 mg/mL of iodixanol) with calcium chloride dihydrate 0.074 mg/mL and sodium chloride 1.87 mg/mL. It is also available at 320 mg/mL of organically bound iodine (as 652 mg/mL of iodixanol) with calcium chloride dihydrate 0.044 mg/mL and sodium chloride 1.11 mg/mL. Each mL of the solutions also contains tromethamine 1.2 mg, edetate calcium disodium 0.1 mg, and hydrochloric acid and/or sodium hydroxide to adjust pH. The products are packaged from 50 to 200 mL.<sup>1(5/06)</sup>

### pH

Adjusted during manufacturing to pH 7.4 with a range from 6.8 to 7.7 at 22°C.<sup>1(5/06)</sup>

### Osmolality

Both concentrations have an osmolality of 290 mOsm/kg.<sup>1(5/06)</sup>

### Density

The 270-mg I/mL product has a density of 1.314 g/mL at 20°C and 1.303 g/mL at 37°C. The 320-mg I/mL product has a density of 1.369 g/mL at 20°C and 1.356 g/mL at 37°C.<sup>1(5/06)</sup>

### Trade Name(s)

Visipaque

### Administration

Iodixanol is administered intravenously and intra-arterially. It is not intended for intrathecal use. The drug may be administered at either body or room temperature.<sup>1(5/06)</sup>

### Stability

Intact containers of clear, colorless to pale yellow iodixanol injection should be stored at controlled room temperature and protected from exposure to direct sunlight and from freezing. Discard the product if inadvertently frozen because of possible damage to closure integrity. The foil overwrap on the flexible plastic containers serves as both a moisture and light barrier and should not be removed until immediately before use. Vials and bottles of iodixanol may be stored for up to one month at 37°C in a contrast agent warmer using circulating warm air.<sup>1(5/06)</sup>

## Iohexol

### AHFS 36:68

### Products

Iohexol is available in concentrations ranging from 30.2% (140 mg/mL organically bound iodine) to 75.5% (350 mg/mL organically bound iodine) in numerous vial and bottle sizes from 10 to 250 mL; not all concentrations are available in all sizes. Also present in each mL are tromethamine 1.21 mg, edetate calcium disodium 0.1 mg, and hydrochloric acid or sodium hydroxide to adjust the pH.<sup>1(1/07)</sup> Table 1 presents the characteristics of iohexol products.

**Table 1. Iohexol product characteristics<sup>1(1/07)</sup>**

Iohexol Concentration (%)	Iodine Concentration (mg/mL)	Osmolality (mOsm/kg)	Specific Gravity (37°C)
30.2	140	322	1.164
38.8	180	408	1.209
51.8	240	520	1.280
64.7	300	672	1.349
75.5	350	844	1.406

### pH

From 6.8 to 7.7.<sup>1(1/07)</sup>

### Trade Name(s)

Omnipaque

### Administration

Iohexol at appropriate concentrations may be administered intravenously, intra-arterially, intrathecally (except for Omnipaque 350) slowly over one to two minutes, intra-articularly, or directly into selected areas for visualization. Solutions should be warmed to body temperature prior to administration.<sup>1(1/07)</sup>

### Stability

Iohexol is colorless to pale yellow. Intact vials should be stored at controlled room temperature and protected from direct exposure to sunlight and freezing. The product should not be used if particulate matter is present. Do not remove the iohexol containers from the moisture- and light-protective foil overwrap until immediately before use.<sup>1(1/07)</sup>

# Iopamidol

AHFS 36:68

## Products

Iopamidol products are available in concentrations ranging from 41% (200 mg/mL organically bound iodine) to 76% (370 mg/mL organically bound iodine) in numerous vial and bottle sizes from 20 to 200 mL; not all concentrations are available in all sizes. Also present in each mL are tromethamine 1 mg, edetate calcium disodium, with hydrochloric acid and/or sodium hydroxide to adjust the pH.<sup>1(3/07)</sup> Table 1 presents the characteristics of Iopamidol products.

**Table 1. Iopamidol product characteristics<sup>1(3/07)</sup>**

Iopamidol Concentration (%)	Iodine Concentration (mg/mL)	Osmolality (mOsm/kg)	Specific Gravity (37°C)
41	200	413	1.227
51	250	524	1.281
61	300	616	1.339
76	370	796	1.405

## pH

From 6.5 to 7.5.<sup>1(3/07)</sup>

## Trade Name(s)

Isovue

## Administration

Iopamidol may be administered intravenously or intra-arterially. Solutions should be warmed to body temperature prior to administration.<sup>1(3/07)</sup>

## Stability

Iopamidol injection is colorless to pale yellow. Intact vials should be stored at controlled room temperature and protected from light. If crystals form, they should be dissolved by warming of the vial in hot (60 to 100°C) water for about five minutes and gentle shaking. The vials should cool to body temperature before use. If crystals fail to dissolve, the vials should be discarded.<sup>1(3/07)</sup>

# Iothalamate Meglumine

AHFS 36:68

## Products

Iothalamate meglumine injection is available as a solution in concentrations ranging from 30 to 60% in vials and bottles in a variety of sizes.<sup>3320 3321 3322</sup> Each mL of the 30% solution (Conray 30) contains iothalamate meglumine 300 mg, edetate calcium disodium 0.11 mg, and monobasic sodium phosphate 0.125 mg.<sup>3320</sup> Each mL of the 43% solution (Conray 43) contains iothalamate meglumine 430 mg, edetate calcium disodium 0.11 mg, and monobasic sodium phosphate 0.115 mg.<sup>3321</sup> Each mL of the 60% solution (Conray) contains iothalamate meglumine 600 mg, edetate calcium disodium 0.09 mg, and monobasic sodium phosphate 0.125 mg.<sup>3322</sup>

Iothalamate meglumine also is available as a 17.2% solution for cystography and cystourethrography; this product is not intended for intravascular or intrathecal administration.<sup>3323</sup>

Some examples of iothalamate meglumine products are listed in Table 1.

**Table 1. Some representative iothalamate meglumine products**<sup>3320 3321 3322 3323</sup>

Iothalamate Meglumine Content (%)	Bound Iodine (mg/mL)	Representative Trade Names
Ureteral solutions (not for intravascular use)		
17.2	81	Cysto-Conray II
Parenteral solutions		
30	141	Conray 30
43	202	Conray 43
60	282	Conray

## Sodium Content

Each mL of iothalamate meglumine 30% solution contains approximately 0.04 mg sodium.<sup>3320</sup>

## pH

Iothalamate meglumine 43%: From 6.6 to 7.6.<sup>3321</sup>

Iothalamate meglumine 30 and 60%: From 6.5 to 7.7.<sup>3320 3322</sup>

## Osmolarity

Iothalamate meglumine 30%: 500 mOsm/L.<sup>3320</sup>

Iothalamate meglumine 43%: 800 mOsm/L.<sup>3321</sup>

Iothalamate meglumine 60%: 1000 mOsm/L.<sup>3322</sup>

## Osmolality

Iothalamate meglumine 30, 43, and 60% solutions are hypertonic, having osmolalities of 600, 800, and 1400 mOsm/kg, respectively.<sup>3320 3321 3322</sup>

## Trade Name(s)

Conray, Conray 30, Conray 43

## Administration

Iothalamate meglumine 30, 43, and 60% solutions may be administered intravenously, intra-arterially, or by injection into pancreatic and biliary ducts, specific to the procedure for which the solution is being employed.<sup>3320 3321 3322</sup> Solutions should be warmed to body temperature prior to administration.<sup>3320 3321 3322</sup> For certain procedures, the manufacturer states that iothalamate meglumine 60% may be diluted with sodium chloride injection or sterile water for injection.<sup>3322</sup>

If a minor reaction occurs during iothalamate meglumine administration, the injection should be slowed or stopped until the reaction has subsided.<sup>3320 3321 3322</sup> If a major reaction occurs, administration of the drug should be discontinued immediately.<sup>3320 3321 3322 3323</sup>

Iothalamate meglumine solutions are *not* indicated for intrathecal administration.<sup>3320 3321 3322 3323</sup> Care must be taken to ensure that the drug is not administered intrathecally.<sup>3320 3321 3322 3323</sup>

Iothalamate meglumine solution 17.2% (Cysto-Conray II) is instilled by gravity flow or syringe into the urinary bladder; this solution should *not* be administered intravascularly or intrathecally.<sup>3323</sup>

## Stability

Iothalamate meglumine solutions are clear.<sup>3320 3321 3322</sup> Iothalamate meglumine 30, 43, and 60% solutions should be stored below 30°C.<sup>3320 3321 3322</sup> Crystallization does not occur at room temperature, but exposure to very cold temperatures may result in crystallization of the salt.<sup>3320 3321 3322</sup> If crystallization occurs, the solution should be brought to room temperature; intermittent<sup>3320</sup> or vigorous shaking<sup>3321 3322</sup> also may be necessary to redissolve the crystals. The speed of dissolution may be increased for some products by heating the vials in circulating warm air.<sup>3321 3322</sup>

The manufacturer states that iothalamate meglumine solutions must not be mixed in the same syringe with corticosteroids or antihistamines due to the potential for chemical incompatibility.<sup>3320 3321 3322</sup>

Iothalamate meglumine solution should be visually inspected for particulate matter or discoloration prior to administration.<sup>3320 3321 3322</sup>

## pH Effects

Iothalamate meglumine is sensitive to low pH values. At reported pH values of about 2.4 to 2.7, turbidity or frank precipitation may appear in the 60% product.<sup>479</sup>

## Light Effects

Iothalamate meglumine solutions are light sensitive and should be protected from strong daylight and direct sunlight.<sup>3320 3321 3322</sup>

## Syringes

Iothalamate meglumine 60% was stored in polystyrene syringes (Pharmaseal) at 25 and 37°C. No apparent changes were noted over 5 days.<sup>530</sup>

Syringe material is one of many factors that may contribute to the development of thromboembolic events that have been

reported with the use of contrast media in angiographic procedures.<sup>3320 3321 3322</sup> The use of plastic syringes rather than glass has been reported to decrease, but not entirely eliminate, the likelihood of in vitro clotting.<sup>3320 3321 3322</sup>

## Ioxaglate Meglumine–Ioxaglate Sodium

AHFS 36:68

### Products

Ioxaglate meglumine 39.3% and Ioxaglate sodium 19.6% (Mallinckrodt) is available in containers ranging in size from 20 to 200 mL. Each mL contains Ioxaglate meglumine 393 mg, Ioxaglate sodium 196 mg, and edetate calcium disodium 0.1 mg. The product provides 32% organically bound iodine.<sup>1(2/05)</sup>

### pH

From 6 to 7.6.<sup>1(2/05)</sup>

### Osmolality

The osmolality of the product is 600 mOsm/kg.<sup>1(2/05)</sup>

### Sodium Content

Each mL provides 0.15 mEq (3.48 mg) of sodium.<sup>1(2/05)</sup>

### Trade Name(s)

Hexabrix

### Administration

The product may be administered intravenously, intra-arterially, or intra-articularly. It also may be injected or instilled directly into selected areas to be visualized. The solutions should be warmed to body temperature before administration.<sup>1(2/05)</sup>

### Stability

The product should be stored below 30°C and protected from freezing and direct exposure to sun or strong daylight. The solution is colorless to pale yellow. Crystallization does not occur at normal room temperatures. If the product is frozen or crystallization occurs, bring it to room temperature and shake vigorously to dissolve all crystals. Warming with circulating warm air is recommended to speed dissolution. Submersion in water is not recommended.<sup>1(2/05)</sup>

**AHFS 10:00**

## Products

Irinotecan hydrochloride is available as a concentrate for injection in 2-, 5-, 15-, and 25-mL single-use vials containing 40, 100, 300, and 500 mg of drug, respectively, on the basis of the trihydrate.<sup>3202 3203</sup> Each mL of solution contains irinotecan hydrochloride trihydrate 20 mg, sorbitol 45 mg, lactic acid 0.9 mg, and hydrochloric acid or sodium hydroxide to adjust the pH in water for injection.<sup>3202 3203</sup> The product must be diluted prior to use.<sup>3202 3203</sup>

Irinotecan hydrochloride concentrate for injection should be visually inspected for particulate matter and discoloration in the vial and again once the solution has been drawn from the vial into the syringe.<sup>3202 3203</sup> Irinotecan hydrochloride concentrate for injection should be diluted to a final concentration of 0.12 to 2.8 mg/mL with dextrose 5% (preferred) or sodium chloride 0.9% prior to administration.<sup>3202 3203</sup>

**CAUTION: Care should be taken to ensure that the correct drug product, dose, and administration procedures are used and that no confusion with other products occurs.**

## pH

Irinotecan hydrochloride concentrate for injection has a pH from 3 to 4.<sup>3202 3203 3204</sup>

## Trade Name(s)

Camptosar

## Administration

Irinotecan hydrochloride is administered by intravenous infusion over 90 minutes after dilution to a final concentration in the range of 0.12 to 2.8 mg/mL in dextrose 5% (preferred) or sodium chloride 0.9%.<sup>3203 3203</sup>

As with other toxic drugs, caution should be exercised in the handling and preparation of irinotecan hydrochloride solutions for infusion.<sup>3202 3203</sup> Manufacturers recommend the use of gloves.<sup>3202 3203</sup> If skin contact with the drug occurs, the affected area(s) should be washed immediately and thoroughly with soap and water; for mucosal membrane contact, the affected(s) area should be flushed thoroughly with water.<sup>3202 3203</sup> Extravasation should be avoided.<sup>3202 3203</sup>

**CAUTION: Care should be taken to ensure that the correct drug product, dose, and administration procedures are used and that no confusion with other products occurs.**

## Stability

Irinotecan hydrochloride injection is a clear pale yellow solution.<sup>3202 3203</sup> Intact vials should be stored upright at controlled room temperature and in the original carton to protect from light until use.<sup>3202 3203</sup>

Manufacturers recommend that diluted solutions of irinotecan hydrochloride for infusion should be used immediately or within 4 hours after dilution if stored at room temperature (in dextrose 5% or sodium chloride 0.9%) or 24 hours if stored at 2 to 8°C (in dextrose 5% only).<sup>3202 3203</sup> Refrigeration of admixtures of the drug prepared with sodium chloride 0.9% should be avoided because of the potential for a low and sporadic incidence of visible particulate formation.<sup>3202 3203</sup>

Irinotecan hydrochloride (Aventis Pharma) 0.35 mg/mL in sodium chloride 0.9% did not result in the loss of viability of *Staphylococcus aureus*, *Enterococcus faecium*, *Pseudomonas aeruginosa*, and *Candida albicans* within 120 hours at room temperature of 22°C. Diluted solutions should be stored under refrigeration whenever possible, and the potential for microbiological growth should be considered when assigning expiration periods.<sup>2740</sup>

## pH Effects

Irinotecan hydrochloride stability is pH dependent. In solution at acidic pH the drug is stable, but neutral and alkaline solutions are problematic. Maximum stability is demonstrated at pH 6 or lower. Increasing solution pH to more than pH 6.5 has resulted in 10% loss in as little as 3 hours. At pH 7.4, decomposition is rapid. Mixing irinotecan hydrochloride with neutral or alkaline drugs and solutions should be avoided.<sup>1881 2274 2375</sup>

## Light Effects

Irinotecan hydrochloride is subject to photodegradation, including the formation of a precipitate. The structural changes exhibited by the decomposition products would indicate that they are unlikely to be active antineoplastic compounds.<sup>1997 1998 2137</sup> Exposure to ultraviolet light for 3 days produced a darkening in the solution color and the formation of a yellow precipitate composed of several decomposition products.<sup>1997</sup> Photodegradation of irinotecan hydrochloride occurs under any pH condition but is accelerated in neutral and alkaline solutions compared with acidic solutions. At pH 10, photodegradation is very rapid; at pH 3 it is much slower. At pH 7, irinotecan 0.34 mg/mL lost 32% in 6 hours exposed to a daylight lamp and 19% exposed to a white fluorescent light. In infusion solutions having neutral pH, irinotecan hydrochloride exposed to lighting (such as that of a medical facility) may have rapid decomposition. Protection from light exposure has been recommended to maintain product quality during administration.<sup>1998</sup> Other researchers have found that unacceptable losses occur within 7 days when exposed to fluorescent light but that light protection during administration is not needed.<sup>2419</sup>

## Freezing Solutions

Precipitation may result from freezing irinotecan hydrochloride concentrate for injection and diluted solutions for infusion; freezing should be avoided.<sup>3202 3203</sup>

## Irinotecan Hydrochloride Liposomal

AHFS 10:00

### Products

Irinotecan hydrochloride liposomal injection is available in 10-mL single-use vials containing 43 mg of irinotecan as the free base in a white to slightly yellow opaque liposomal dispersion.<sup>3147</sup> Irinotecan is provided inside liposome carriers (approximate diameter 110 nm) in a gelated or precipitated state as the sucrose octasulfate salt.<sup>3147</sup> Liposomes encapsulating irinotecan are composed of distearoyl phosphatidylcholine (DSPC) 6.81 mg/mL, cholesterol 2.22 mg/mL, and methoxy-terminated polyethylene glycol 2000 distearoylphosphatidyl ethanolamine (MPEG-2000-DSPE) 0.12 mg/mL.<sup>3147</sup> Each vial also contains sodium chloride 8.42 mg/mL and hydroxyethylpiperazine ethane sulfonic acid (HEPES) 4.05 mg/mL.<sup>3147</sup>

**CAUTION:** Care should be taken to ensure that the correct drug product, dose, and administration procedures are used and that no confusion with other products occurs. The manufacturer states that irinotecan hydrochloride liposomal injection *must not* be substituted for other drugs containing irinotecan hydrochloride.<sup>3147</sup>

The appropriate dose of the drug should be withdrawn from the vial and diluted in 500 mL of dextrose 5% or sodium chloride 0.9%.<sup>3147</sup> The diluted solution should be mixed by gentle inversion.<sup>3147</sup>

### Tonicity

Irinotecan hydrochloride liposomal injection is isotonic.<sup>3147</sup>

### Trade Name(s)

Onivyde

## Compatibility Information

### Solution Compatibility

### Administration

Irinotecan hydrochloride liposomal injection is administered by intravenous infusion over 90 minutes following dilution in dextrose 5% or sodium chloride 0.9%.<sup>3147</sup> If solutions diluted for infusion have been refrigerated, the solution should be allowed to come to room temperature prior to administration.<sup>3147</sup> Diluted solutions should be protected from light.<sup>3147</sup>

As with other toxic drugs, applicable special handling and disposal procedures for irinotecan hydrochloride liposomal should be followed.<sup>3147</sup>

**CAUTION:** Care should be taken to ensure that the correct drug product, dose, and administration procedures are used and that no confusion with other products occurs.

### Stability

Intact vials of irinotecan hydrochloride liposomal injection should be stored at 2 to 8°C.<sup>3147</sup> Both intact vials and solutions diluted for infusion should be protected from light and should not be frozen.<sup>3147</sup> The manufacturer states that diluted solutions should be used within 4 hours after dilution if stored at room temperature or within 24 hours if refrigerated at 2 to 8°C.<sup>3147</sup> Any unused portions of the solution should be discarded.<sup>3147</sup>

### Filtration

Inline filters should *not* be used for administration of irinotecan hydrochloride liposomal injection.<sup>3147</sup>

## Iron Dextran

### AHFS 20:04.04

### Products

Iron dextran injection is available as a dark brown liquid complex of ferric hydroxide and dextran in 2-mL single-dose vials.<sup>3575</sup> Each mL contains the equivalent of 50 mg of elemental iron in sodium chloride approximately 0.9% and water for injection.<sup>3575</sup> Sodium hydroxide and/or hydrochloric acid may have been used to adjust the pH.<sup>3575</sup>

### pH

The pH of the solution ranges from 4.5 to 7.<sup>3575</sup>

### Trade Name(s)

INFeD

### Administration

Iron dextran is administered intravenously and intramuscularly.<sup>3575</sup> With either route of administration, a test dose should be administered prior to the first therapeutic dose.<sup>3575</sup>

Iron dextran may be administered undiluted by slow intravenous injection.<sup>3575</sup> A test dose of 0.5 mL (25 mg of elemental iron) should be administered at a gradual rate over at least 30 seconds prior to the first therapeutic dose of iron dextran.<sup>3575</sup> If no signs or symptoms of anaphylactic-type reactions have occurred after a period of at least one hour has elapsed, the remainder of the initial therapeutic dose (i.e., the therapeutic dose less the test dose) may be administered at a slow, gradual rate of no more than 1 mL (50 mg of elemental iron)/min.<sup>3575</sup>

Iron dextran also may be administered by deep intramuscular injection into the upper outer quadrant of the buttock using a 2- or 3-inch, 19- or 20-gauge needle.<sup>3575</sup> Staining of the skin associated with inadvertent injection or leakage of the drug into the subcutaneous tissue can be minimized by displacing

the skin laterally prior to intramuscular injection (i.e., Z-track technique).<sup>3575</sup> A test dose of 0.5 mL (25 mg of elemental iron) should be administered in the buttock prior to the first therapeutic dose of iron dextran.<sup>3575</sup> If no signs or symptoms of anaphylactic-type reactions have occurred after a period of at least one hour has elapsed, the remainder of the initial therapeutic dose (i.e., the therapeutic dose less the test dose) may be administered.<sup>3575</sup> Subsequent injections should be made into alternate buttocks.<sup>3575</sup>

Iron dextran also has been administered by intravenous infusion over 1 to 6 hours after dilution in sodium chloride 0.9% (e.g., 1 g diluted in 250 mL of sodium chloride 0.9% administered over 1 hour).<sup>3576 3577 3578 3579 3580</sup>

Dilution in dextrose 5% results in a greater incidence of pain and phlebitis.<sup>75</sup> The manufacturer recommends not adding iron dextran injection to parenteral nutrition solutions,<sup>3575</sup> especially 3-in-1 mixtures.<sup>1814</sup>

### Stability

Intact vials of iron dextran injection should be stored at controlled room temperature.<sup>3575</sup>

### Filtration

Iron dextran adsorbs to sterilizing membrane filters composed of cellulose nitrate and acetate combined. An iron dextran solution containing 5 mcg/mL in water was estimated to lose 93% of the iron from the first mL passed through the filter. As more solution was passed through the filter, a decreasing proportion of the iron was adsorbed, indicating that the filter was approaching saturation. The extent of iron adsorption increased in the presence of electrolytes and trace elements. Adsorption can be substantial, especially when small amounts of iron dextran are involved.<sup>918</sup>

## Iron Sucrose

AHFS 20:04.04

### Products

Iron sucrose injection is available as a brown solution in 2.5-, 5-, and 10-mL single-dose (preservative-free) vials containing 50, 100, and 200 mg of elemental iron, respectively.<sup>3551</sup> Each mL of the solution contains 20 mg of elemental iron and 300 mg of sucrose in water for injection.<sup>3551</sup>

### pH

Iron sucrose injection has a pH ranging from 10.5 to 11.1.<sup>3551</sup>

### Osmolarity

Iron sucrose injection has an osmolarity of 1250 mOsmol/L.<sup>3551</sup>

### Trade Name(s)

Venofer

### Administration

Iron sucrose is administered only intravenously, as an injection or an infusion.<sup>3551</sup> Stable intravenous access should be insured to avoid extravasation.<sup>3551</sup>

In adults, doses of elemental iron up to 200 mg can be administered undiluted as a slow intravenous injection over 2 to 5 minutes; doses of 100 or 200 mg also may be administered as an intravenous infusion over at least 15 minutes following dilution of the dose in a maximum of 100 mL of sodium chloride 0.9%.<sup>3551</sup> Doses of elemental iron of 300 or 400 mg should be administered as an intravenous infusion over 1.5 or 2.5 hours, respectively, following dilution of the dose in a maximum of 250 mL of sodium chloride 0.9%.<sup>3551</sup> The manufacturer states that there is limited experience with the administration of 500-mg

doses of elemental iron as an intravenous infusion over 3.5 to 4 hours following dilution of the dose in a maximum of 250 mL of sodium chloride 0.9%.<sup>3551</sup>

In pediatric patients 2 years of age or older, doses of elemental iron up to 100 mg can be administered undiluted as a slow intravenous injection over 5 minutes or as an intravenous infusion over 5 to 60 minutes following dilution of the dose to an elemental iron concentration of 1 to 2 mg/mL in sodium chloride 0.9%.<sup>3551</sup>

Iron sucrose injection should *not* be diluted to an elemental iron concentration of less than 1 mg/mL.<sup>3551</sup>

### Stability

Intact vials of iron sucrose should be stored at controlled room temperature; freezing should be avoided.<sup>3551</sup>

Iron sucrose injection should *not* be diluted to an elemental iron concentration of less than 1 mg/mL.<sup>3551</sup>

Iron sucrose injection should be visually inspected for particulate matter and discoloration prior to administration.<sup>3551</sup> The manufacturer states that iron sucrose injection should not be mixed with other drugs or added to parenteral nutrition solutions for intravenous infusion.<sup>3551</sup>

### Syringes

Iron sucrose (American Regent) containing 20 mg/mL of elemental iron undiluted or diluted to concentrations ranging from 2 to 10 mg/mL in sodium chloride 0.9% and stored in plastic syringes was found to be physically and chemically stable for 7 days at 23 to 27°C and 2 to 6°C.<sup>3551</sup>

## Isavuconazonium Sulfate

AHFS 8:14.08

### Products

Isavuconazonium sulfate is a prodrug that is metabolized in vivo to isavuconazole.<sup>3006</sup> Isavuconazonium sulfate is available as a lyophilized powder in single-use (preservative-free) vials containing 372 mg of the drug (equivalent to 200 mg of isavuconazole) and mannitol 96 mg.<sup>3006</sup> Sulfuric acid also is present to adjust the pH.<sup>3006</sup>

Each 372-mg vial of isavuconazonium sulfate should be reconstituted with 5 mL of sterile water for injection and gently shaken to completely dissolve the powder.<sup>3006</sup> The reconstituted solution should be visually inspected for particulate matter and discoloration.<sup>3006</sup> To prepare a 372-mg dose, 5 mL of the reconstituted solution should be withdrawn from the vial and added to an infusion bag containing 250 mL of sodium chloride 0.9% or dextrose 5%, yielding an approximate isavuconazonium sulfate concentration of 1.5 mg/mL.<sup>3006</sup>

Visible translucent to white insoluble particulates of isavuconazole may form in diluted solutions of the drug.<sup>3006</sup> The diluted solution should be gently mixed or rolled to minimize the formation of such particulates.<sup>3006</sup> Any unnecessary vibration or vigorous shaking should be avoided; pneumatic transport systems should *not* be used.<sup>3006</sup> The final diluted solution *must* be administered through a 0.2- to 1.2- $\mu$ m inline filter to remove isavuconazole particulates.<sup>3006</sup> A reminder sticker regarding the need for an inline filter should be affixed to the infusion bag.<sup>3006</sup>

### Trade Name(s)

Cresemba

### Administration

Isavuconazonium sulfate should be administered by intravenous infusion over at least 1 hour after dilution in 250 mL of

sodium chloride 0.9% or dextrose 5%.<sup>3006</sup> The drug should *not* be administered by intravenous bolus injection.<sup>3006</sup>

The final diluted solution of isavuconazonium sulfate *must* be administered through a 0.2- to 1.2- $\mu$ m inline filter.<sup>3006</sup> The drug should not be infused with other intravenous medications; if a common infusion line is being used to administer other drugs, the line should be flushed with sodium chloride 0.9% or dextrose 5% prior to and following infusion of isavuconazonium sulfate.<sup>3006</sup>

### Stability

Intact vials of isavuconazonium sulfate should be stored under refrigeration at 2 to 8°C.<sup>3006</sup> Isavuconazonium sulfate is a white to yellow powder that forms a clear solution when reconstituted with sterile water for injection.<sup>3006</sup>

The manufacturer states that the reconstituted solution should be used immediately, but may be stored below 25°C for up to 1 hour prior to dilution.<sup>3006</sup> The total time for storage (of the diluted solution in the infusion bag) and the infusion time together should not exceed 6 hours if stored at room temperature or 24 hours if stored at 2 to 8°C.<sup>3006</sup> The infusion solution should *not* be frozen.<sup>3006</sup>

### Filtration

The diluted solution for infusion *must* be administered with an infusion set containing a 0.2- to 1.2- $\mu$ m inline filter to remove insoluble isavuconazole particulates that may form in diluted solutions of the drug.<sup>3006</sup>

# Isoproterenol Hydrochloride

AHFS 12:12.08.04

## Isoprenaline Hydrochloride

### Products

Isoproterenol hydrochloride is available at a concentration of 0.2 mg/mL in 1- and 5-mL ampuls.<sup>2903</sup> In addition to the drug, each mL contains sodium chloride 7 mg, sodium citrate dihydrate 2.07 mg, citric acid anhydrous 2.5 mg, edetate disodium 0.2 mg, and hydrochloric acid or sodium hydroxide to adjust the pH in water for injection.<sup>2903</sup>

### pH

From 3.5 to 4.5.<sup>2903</sup>

### Osmolality

The osmolality of isoproterenol hydrochloride 0.2 mg/mL was determined to be 277 mOsm/kg by freezing-point depression and 293 mOsm/kg by vapor pressure.<sup>1071</sup>

### Trade Name(s)

Isuprel

### Administration

Isoproterenol hydrochloride may be administered by intravenous infusion; by direct intravenous, intramuscular, or subcutaneous injection; and, in extreme emergencies, by intracardiac injection.<sup>2903</sup> For direct intravenous injection, 1 mL of the 0.2-mg/mL injection should be diluted to 10 mL with sodium chloride 0.9% or dextrose 5% to provide a 20-mcg/mL solution.<sup>2903</sup> Intravenous infusions are prepared by diluting 5 or 10 mL of the 0.2-mg/mL injection in 500 mL of dextrose 5% to yield solutions containing 2 or 4 mcg/mL, respectively.<sup>2903</sup> Intravenous infusion concentrations of up to 20 mcg/mL have been used when fluid restriction is essential.<sup>2903</sup>

For intramuscular, subcutaneous, and intracardiac injection, isoproterenol hydrochloride should be administered undiluted.<sup>2903</sup>

### Stability

Isoproterenol hydrochloride injection in intact containers should be stored at controlled room temperature and protected from light.<sup>2903</sup> Ampuls should be kept in opaque containers until use.<sup>2903</sup> The drug should not be used if the solution is pinkish or slightly darker than yellow or if a precipitate is present.<sup>2903</sup> Exposure to air, light, or increased temperature may cause a pink to brownish pink color to develop.<sup>4 975</sup>

Isoproterenol hydrochloride under simulated summer conditions in paramedic vehicles was exposed to temperatures ranging from 26 to 38°C over 4 weeks. Analysis found about 4% loss of the drug in 7 days and 11% loss in 4 weeks.<sup>2562</sup>

### pH Effects

The pH of a solution is the primary determinant of catecholamine stability in intravenous admixtures.<sup>527</sup> Isoproterenol hydrochloride 5 mg/L in dextrose 5% was stable for more than 24 hours at 25°C over a pH range of 3.7 to 5.7.<sup>59 3026</sup> However, isoproterenol hydrochloride displayed significant decomposition at a pH value above approximately 6.<sup>48 59 430</sup> If drugs that may raise the pH above 6 are mixed, they should be administered immediately after preparation,<sup>59</sup> or, preferably, administered separately.<sup>24</sup>

Visual inspection for color changes related to decomposition may be inadequate to assess the compatibility of admixtures. In one evaluation with aminophylline stored at 25°C, a color change was not noted until 24 hours had elapsed. However, no intact isoproterenol hydrochloride was present in the admixture at 24 hours.<sup>527</sup>

### Filtration

Isoproterenol hydrochloride (Winthrop) 2 mg/L in dextrose 5%, sodium chloride 0.9%, and Ringer's injection, lactated, filtered over 12 hours through a 5- $\mu$ m stainless steel depth filter (Argyle Filter Connector), a 0.22- $\mu$ m cellulose ester membrane filter (Ivex-2 Filter Set) and a 0.22- $\mu$ m polycarbonate membrane filter (In-Sure Filter Set) showed no significant reduction due to binding to the filters.<sup>320</sup>

In another study, isoproterenol hydrochloride (Winthrop) 4 mg/L in dextrose 5% and sodium chloride 0.9% did not display significant sorption to a 0.45- $\mu$ m cellulose membrane filter (Abbott S-A-I-F) during an 8-hour simulated infusion.<sup>567</sup>

### Central Venous Catheter

Isoproterenol hydrochloride (Abbott) 0.02 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

### Solution Compatibility

#### Isoproterenol HCl

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Amino acids 4.25%, dextrose 25%	MG	WI	2 mg	No increase in particulate matter in 24 hr at 5°C	349	C
Dextrose 5%	AB	BN	2 mg	Physically compatible and chemically stable. 10% decomposition is calculated to occur in 24 hr in the light and 250 hr in the dark at 25°C	527	C
Dextrose 5%		HOS	2 and 4 mg	Manufacturer recommended solution	2903	C

### Additive Compatibility

#### Isoproterenol HCl

Test Drug	Mfr	Conc/L or %	Mfr	Conc/L or %	Test Solution	Remarks	Ref	C/I
Aminophylline	SE	500 mg	BN	2 mg	D5W	At 25°C, 10% isoproterenol decomposition in 2.2 to 2.5 hr in light and dark	527	I
Atracurium besylate	BW	500 mg		4 mg	D5W	Physically compatible and atracurium stable for 24 hr at 5 and 30°C	1694	C

AHFS 24:12.08

## Products

Isosorbide dinitrate is available as a 0.1% concentrate for injection in 10-mL ampuls and 50- and 100-mL vials and bottles; each mL contains isosorbide dinitrate 1 mg with sodium chloride in water for injection.<sup>3573 3574</sup> Hydrochloric acid and sodium hydroxide may be present to adjust the pH.<sup>3573</sup> The concentrate for injection *must* be diluted prior to intravenous administration.<sup>3573 3574</sup> Manufacturers state that 50 mL (50 mg) of isosorbide dinitrate 0.1% concentrate for injection may be diluted in 450 mL of a compatible infusion solution for a final isosorbide dinitrate concentration of 0.1 mg/mL.<sup>3573 3574</sup> If reduced fluid intake is necessary, 100 mL (100 mg) of isosorbide dinitrate 0.1% concentrate for injection may be diluted to a total volume of 500 mL using a compatible infusion solution for a final isosorbide dinitrate concentration of 0.2 mg/mL; if fluid intake is strictly limited, a 50% dilution of the concentrate for injection (i.e., to a final isosorbide dinitrate concentration of 0.5 mg/mL) is recommended.<sup>3573 3574</sup>

The drug also is available as a 0.05% solution in 50-mL vials and bottles and 10-mL prefilled syringes; each mL contains isosorbide dinitrate 0.5 mg with sodium chloride in water for injection.<sup>3571 3572</sup> Hydrochloric acid and sodium hydroxide also may be present to adjust the pH.<sup>3571</sup>

## Sodium Content

Each mL of isosorbide dinitrate 0.05 or 0.1% solution contains 3.54<sup>3571 3572 3573</sup> or 3.6 mg<sup>3574</sup> of sodium.

## Trade Name(s)

Isoket, Risordan

## Administration

Isosorbide dinitrate is administered by intravenous infusion.<sup>3571 3572 3573 3574</sup> Only the 0.05% solution may be administered undiluted by slow infusion using a syringe pump; alternatively, the 0.05% solution may be diluted in a compatible infusion solution for administration.<sup>3571 3572</sup> The 0.1% concentrate for injection *must* be diluted in a compatible infusion solution prior to intravenous administration.<sup>3573 3574</sup>

Isosorbide dinitrate also may be administered as an intracoronary bolus injection during percutaneous transluminal coronary angioplasty.<sup>3571 3572 3573 3574</sup> Manufacturers recommend a 50% dilution of the 0.1% concentrate for injection (i.e., to a final isosorbide dinitrate concentration of 0.5 mg/mL) if administered by the intracoronary route.<sup>3573 3574</sup>

## Stability

Once opened, containers should be used immediately, and any remainder should be discarded.<sup>3571 3572 3573 3574</sup> Specific product labeling should be consulted for additional storage details.

One manufacturer (Merus Labs) states that isosorbide dinitrate diluted in a compatible infusion solution (e.g., sodium chloride

[concentration unspecified], dextrose 5 to 30%, Ringer's injection) is physically and chemically stable for 24 hours at 2 to 8°C.<sup>3571 3573</sup> Another manufacturer (Torbay) states that isosorbide dinitrate diluted in sodium chloride (concentration unspecified) or dextrose (concentration unspecified) has been shown to be physically and chemically stable for 72 hours at 25°C when stored protected from light in polypropylene or glass containers.<sup>3572 3574</sup>

## Syringes

Isosorbide dinitrate (Rhone-Poulenc) 1 mg/mL was repackaged in polypropylene syringes (Plastipak, Becton Dickinson) and stored for 8 hours at room temperature and 4°C. No loss of drug was found.<sup>1799</sup>

Isosorbide dinitrate (Takeda) 30 mg/50 mL in sodium chloride 0.9% in a 50-mL polypropylene syringe (BD) was physically stable for 48 hours at room temperature.<sup>3545</sup>

Isosorbide dinitrate (Takeda) 0.6 mg/mL in sodium chloride 0.9% in a 50-mL polypropylene syringe (BD) was physically stable with a mean loss of 5.4% in 28 days at 2 to 8°C protected from light.<sup>3570</sup>

## Sorption

Isosorbide dinitrate undergoes rapid and extensive sorption to polyvinyl chloride (PVC) and polyamide containers and PVC administration tubing. Studies have reported isosorbide dinitrate losses ranging from about 15 to 50%, depending on concentration, flow rate, contact time, length of tubing, and temperature. The majority of loss occurs at the beginning of contact with the plastic and then declines as saturation occurs. Isosorbide dinitrate also undergoes sorption of about 16 to 26% to cellulose propionate and butadiene styrene burette chambers but only 2% to methacrylate butadiene styrene burette chambers. However, little or no sorption occurs to glass, polyethylene, polybutadiene, nylon, and polypropylene containers and administration equipment. Consequently, glass, polyethylene, polypropylene, polybutadiene, and polytetrafluoroethylene containers and equipment are recommended while PVC, polyurethane, and polyamide are not.<sup>769 782 795 1027 1392 1464 1465 1466 1467 1619 2143 2289 3571 3572 3573 3574</sup>

## Filtration

Losses due to sorption of isosorbide dinitrate 250 mg/L in sodium chloride 0.9% delivered at 20 mL/hr through cellulose acetate filters (Sterifix, Ivex HP) were 15 to 26%. Losses to polyamide filters (Pall) were 9 to 13% under the same conditions.<sup>1465</sup>

The loss of isosorbide dinitrate due to sorption to filters extends to filters used in hemodialysis. Isosorbide dinitrate 0.1 mg/mL in sodium chloride 0.9% during simulated hemodialysis using 5 different filter media underwent substantial drug losses from the solution and binding to some of the filters. Losses of approximately 86% with polysulfone (Fresenius), 72% with cellulose acetate (Baxter), 43% with polyacrylonitrile (Hospal), and 12% cuprophane (Gambro) were found. However, with hemophan filters (Gambro), no loss of drug due to sorption occurred.<sup>2138</sup>

# Ketamine Hydrochloride

AHFS 28:04.92

## Products

Ketamine hydrochloride is available in concentrations equivalent to 10, 50, or 100 mg/mL of ketamine in 20-, 10-, or 5-mL multidose vials, respectively.<sup>3116 3117</sup> The injections also contain no more than 0.1 mg/mL of the preservative benzethonium chloride.<sup>3116 3117</sup>

The 10-mg/mL concentration should not be diluted.<sup>3116</sup> However, the 100-mg/mL injection is a concentrate and *must* be diluted prior to intravenous use.<sup>3116 3117</sup> Doses should be diluted with an equal volume of sterile water for injection, dextrose 5%, or sodium chloride 0.9%.<sup>3116 3117</sup>

## pH

From 3.5 to 5.5.<sup>3116 3117</sup>

## Tonicity

The 10-mg/mL concentration is made isotonic with sodium chloride.<sup>3116</sup>

## Osmolality

The osmolalities of ketamine hydrochloride products were determined to be 300 mOsm/kg for the 10-mg/mL concentration and 387 mOsm/kg for the 50-mg/mL concentration.<sup>1233</sup>

## Trade Name(s)

Ketalar

## Administration

Ketamine hydrochloride may be administered intramuscularly or by slow intravenous injection over 60 seconds.<sup>3116 3117</sup> The 100-mg/mL preparation should not be administered without proper dilution.<sup>3116 3117</sup> For intravenous infusion, a 1- or 2-mg/mL solution may be prepared by adding 500 mg of ketamine to 500 or 250 mL, respectively, of dextrose 5% or sodium chloride 0.9%.<sup>3116 3117</sup>

Diazepam and barbiturates must be administered separately from ketamine hydrochloride and must not be mixed in the same container.<sup>3116 3117</sup>

## Stability

Intact vials of ketamine hydrochloride should be stored at controlled room temperature and protected from light.<sup>3116 3117</sup>

Ketamine hydrochloride injection varies from colorless to very slightly yellow.<sup>3117</sup> The drug may darken upon prolonged exposure to light; however, this darkening does not affect potency.<sup>3117</sup> The product should be visually inspected for particulate matter and discoloration prior to administration and should not be used if a precipitate appears.<sup>3117</sup>

Ketamine hydrochloride (Sandoz) prepared at a ketamine concentration of 10 mg/mL diluted in sterile water for injection was packaged in 5-mL glass vials and stored at room temperature with exposure to light for 182 days.<sup>3118</sup> The solution remained clear and without discoloration and less than 4% drug loss occurred.<sup>3118</sup>

## Syringes

Ketamine hydrochloride (Abbott) prepared at a ketamine concentration of 10 mg/mL diluted in sterile water for injection was packaged in 1-mL polypropylene tuberculin syringes (Becton Dickinson) and was stored at 25°C.<sup>2431</sup> The drug solution remained clear and no loss occurred in 30 days.<sup>2431</sup>

Ketamine hydrochloride (Fagron) prepared at a ketamine concentration of 1 mg/mL diluted in sodium chloride 0.9% was packaged in polypropylene syringes with tip caps and stored at 4, 25, and 40°C for 12 months.<sup>2779</sup> No visible changes occurred, and drug concentrations remained above 95% at all temperatures.<sup>2779</sup>

Ketamine hydrochloride (Pfizer) undiluted at a ketamine concentration of 50 mg/mL was packaged as 1 mL in 3-mL polypropylene syringes (Terumo).<sup>3194</sup> The syringes were stored at 25°C protected from light for 180 days.<sup>3194</sup> Solutions were physically stable with no substantial changes in pH or optical density throughout the study.<sup>3194</sup> Little loss of the drug occurred in 180 days.<sup>3194</sup>

Ketamine hydrochloride (Pfizer) undiluted at a ketamine concentration of 50 mg/mL was packaged as 1 mL in 3-mL syringes (Becton Dickinson).<sup>3584</sup> The syringes were stored at room temperature for 50 days.<sup>3584</sup> Solutions were physically stable with no substantial changes in pH or spectrophotometric measurements throughout the study.<sup>3584</sup> Less than 10% loss of the drug occurred in 50 days.<sup>3584</sup>

## Ketorolac Tromethamine

AHFS 28:08.04.92

### Products

Ketorolac tromethamine is available as a 15-mg/mL solution in 1-mL vials and also as a 30-mg/mL solution in 1-mL vials. Ketorolac tromethamine 30 mg/mL is also available in 2-mL vials for intramuscular use. In addition to ketorolac tromethamine, the formulations contain ethanol, sodium chloride, and citric acid in water for injection. The product also contains sodium hydroxide or hydrochloric acid to adjust the pH.<sup>1(6/08)</sup>

### pH

From 6.9 to 7.9.<sup>1(6/08)</sup> 4

### Tonicity

Both ketorolac tromethamine concentrations are isotonic.<sup>4</sup>

### Administration

Ketorolac tromethamine is administered slowly by deep intramuscular injection or by intravenous injection over no less than 15 seconds.<sup>1(6/08)</sup> 4 The 60 mg/2 mL injection is for intramuscular use only.<sup>1(6/08)</sup>

### Stability

Ketorolac tromethamine injection should be stored at controlled room temperature and protected from light. The injection is clear and has a slight yellow color.<sup>1(6/08)</sup> 4 Prolonged exposure to light may result in discoloration of the solution and precipitation.<sup>4</sup> Ketorolac tromethamine is chemically stable over a wide pH range from about pH 3 to 11<sup>499</sup>, but precipitation may occur in solutions and with drugs having a relatively low pH.<sup>4</sup>

# Labetalol Hydrochloride

AHFS 24:24

## Products

Labetalol hydrochloride is available in 20- and 40-mL multiple-dose vials and 4- and 8-mL vials and disposable syringes. Each mL of solution contains labetalol hydrochloride 5 mg, dextrose, anhydrous 45 mg, edetate disodium 0.1 mg, methylparaben 0.8 mg, propylparaben 0.1 mg, and citric acid anhydrous and sodium hydroxide as necessary to adjust pH in water for injection.<sup>1(2/07)</sup>

### pH

From 3 to 4.5.<sup>17</sup>

## Administration

Labetalol hydrochloride is administered by slow direct intravenous injection, over 2 minutes, or by continuous intravenous infusion at an initial rate of 2 mg/min with subsequent adjustments

based on blood pressure response. For continuous infusion, concentrations of 1 mg/mL or 2 mg/3 mL can be made by adding 200 mg (40 mL) to 160 or 250 mL of compatible infusion solution. To facilitate the infusion of labetalol hydrochloride at an accurate rate of administration, a controlled-infusion device, such as a pump, may be used.<sup>1(2/07) 4</sup>

## Stability

Labetalol hydrochloride may be stored at room temperature or under refrigeration and should be protected from light and freezing. The solution is clear and colorless to slightly yellow.<sup>1(2/07)</sup>

### pH Effects

Labetalol hydrochloride has optimal stability at pH 3 to 4. Addition to an alkaline drug or solution has resulted in precipitate formation.<sup>757 1715 2062</sup>

## Lacosamide

AHFS 28:12.92

### Products

Lacosamide is available as a 10-mg/mL solution in 20-mL single-use vials.<sup>3201</sup> Each vial also contains sodium chloride, water for injection, and hydrochloric acid to adjust the pH.<sup>3201</sup> Solutions containing particulate matter or those in which discoloration has occurred should not be used.<sup>3201</sup> Any unused portion should be discarded.<sup>3201</sup>

### pH

Lacosamide 10-mg/mL solution has an adjusted pH from 3.5 to 5.<sup>3201</sup>

### Trade Name(s)

Vimpat

### Administration

Lacosamide is administered intravenously as an infusion either undiluted or diluted in a compatible infusion solution over a period of 15 to 60 minutes.<sup>3201</sup> (See Solution Compatibility.) The manufacturer states that a 30- to 60-minute infusion is preferred when a 15-minute administration is not required.<sup>3201</sup>

### Stability

Lacosamide is a clear, colorless solution.<sup>3201</sup> Intact vials should be stored at controlled room temperature and protected from freezing.<sup>3201</sup>

Lacosamide diluted for infusion in a compatible infusion solution should not be stored for more than 4 hours at room temperature.<sup>3201</sup>

## Compatibility Information

## Lefamulin Acetate

AHFS 8:12.28.26

### Products

Lefamulin acetate is available as a concentrate for injection in single-dose vials containing 15 mL of the concentrate packaged with a 250-mL bag of 10 mM citrate-buffered sodium chloride 0.9% (pH 5) diluent.<sup>3513</sup> Each mL of the concentrate for injection contains 10 mg of lefamulin (as the acetate) in sodium chloride 0.9%.<sup>3513</sup> Each mL of the diluent contains sodium chloride 9 mg, trisodium citrate dihydrate 2 mg, and citric acid anhydrous 0.615 mg in water for injection.<sup>3513</sup>

To prepare the drug for intravenous infusion, the entire contents of the vial containing the concentrate for injection (i.e., 15 mL [150 mg of lefamulin]) should be transferred to the accompanying diluent bag.<sup>3513</sup>

### Equivalency

Lefamulin acetate 168 mg is equivalent to 150 mg of lefamulin.<sup>3513</sup>

### pH

The provided 10 mM citrate-buffered sodium chloride 0.9% diluent has a pH ranging from 4.5 to 5.5.<sup>3513</sup>

### Osmolality

The provided 10 mM citrate-buffered sodium chloride 0.9% diluent has an osmolality of 280 to 340 mOsm/kg.<sup>3513</sup>

### Sodium Content

The provided 10 mM citrate-buffered sodium chloride 0.9% diluent has a sodium content of 174 mEq/L.<sup>3513</sup>

### Trade Name(s)

Xenleta

### Administration

Lefamulin acetate is administered intravenously by infusion over 60 minutes following dilution of the concentrate for injection.<sup>3513</sup>

### Stability

Both the concentrate for injection and the provided diluent are clear, colorless solutions.<sup>3513</sup> Intact vials of lefamulin acetate should be stored at 2 to 8°C and should *not* be frozen.<sup>3513</sup> The manufacturer states that the accompanying diluent bag should be stored at controlled room temperature;<sup>3513</sup> however, such bags also may be stored at 2 to 25°C.<sup>3518</sup>

Lefamulin acetate diluted in the accompanying citrate-buffered sodium chloride 0.9% diluent can be stored for up to 24 hours at room temperature and up to 48 hours under refrigeration at 2 to 8°C.<sup>3513</sup>

## Lenograstim

AHFS 20:16

### Products

Lenograstim (rHuG-CSF) is available as a lyophilized powder in single-use vials containing 13.4 million international units (Granocyte-13) or 33.6 million international units (Granocyte-34). In addition to lenograstim, each vial of the product contains mannitol 2.5%, arginine 1%, phenylalanine 1%, methionine 0.1%, polysorbate 20 0.01%, and hydrochloric acid to adjust pH.<sup>38</sup>

Lenograstim vials of either strength should be reconstituted with 1.05 mL of the accompanying water for injection diluent. Gently mix to effect dissolution, usually about 5 seconds. Do not shake the vials vigorously. Both the lenograstim vials and the diluent are overfilled by 5% to permit withdrawal of a full 1 mL of the reconstituted product containing 13.4 or 33.6 million international units.<sup>38</sup>

### Units

Each 13.4-million international unit vial contains 105 mcg of lenograstim. Each 33.6-million international unit vial contains 263 mcg of lenograstim.<sup>38</sup>

### pH

The reconstituted solution has a pH buffered to 6.5.<sup>38</sup>

### Trade Name(s)

Granocyte-13, Granocyte-34

### Administration

Lenograstim is administered by subcutaneous injection and intravenous infusion after dilution in sodium chloride 0.9% in glass or polyvinyl chloride (PVC) containers or dextrose 5%

in glass containers. Granocyte-13 should not be diluted to a concentration lower than 0.26 million international units/mL (2 mcg/mL); Granocyte-34 should not be diluted to a concentration lower than 0.32 million international units/mL (2.5 mcg/mL). The dilution volume should not exceed 50 mL for each vial of Granocyte-13 and 100 mL for each vial of Granocyte-34.<sup>38</sup>

### Stability

Intact vials of lenograstim should be stored at 30°C or below and protected from freezing. When reconstituted as directed, lenograstim is stable for 24 hours under refrigeration. Diluted for administration to concentrations not less than 0.26 million international units/mL (Granocyte-13) or 0.32 million international units/mL (Granocyte-34), lenograstim is stable for up to 24 hours at 5 or 25°C.<sup>38</sup>

At concentrations not less than 0.26 million international units/mL (Granocyte-13) or 0.32 million international units/mL (Granocyte-34), lenograstim is stable for up to 24 hours at 5 or 25°C in sodium chloride 0.9% in both PVC and glass containers and in dextrose 5% in glass containers.<sup>38</sup>

### Ambulatory Pumps

The stability of lenograstim (Rhône-Poulenc Rorer) 33.6 million international units (263 mcg) and 67.2 million international units (526 mcg) each in 100 mL of sodium chloride 0.9% filled into Intermate elastomeric infusion devices (Baxter) was evaluated stored at 4°C for 14 days. No loss of lenograstim was found.<sup>2048</sup>

### Sorption

Lenograstim prepared in sodium chloride 0.9% is compatible with PVC containers and common administration sets.<sup>38</sup>

Selected Revisions June 1, 2019. © Copyright, October 1998. American Society of Health-System Pharmacists, Inc.

# Letermovir

AHFS 8:18.92

## Products

Letermovir is available as a 20-mg/mL concentrate for injection in single-dose (preservative-free) vials containing 240 mg (12 mL) or 480 mg (24 mL) of the drug, respectively, packaged in 30-mL vials.<sup>3398</sup> Each mL of concentrate for injection also contains hydroxypropyl-beta-cyclodextrin 150 mg, sodium chloride 3.1 mg, and sodium hydroxide in water for injection.<sup>3398</sup> The amount of sodium hydroxide used to adjust the pH may vary.<sup>3398</sup>

Letermovir concentrate for injection must be diluted prior to administration.<sup>3398</sup> The appropriate volume of the concentrate should be withdrawn from the vial and transferred to an infusion bag containing 250 mL of sodium chloride 0.9% or dextrose 5%.<sup>3398</sup> The diluted solution for infusion should be gently mixed and should *not* be shaken.<sup>3398</sup>

## pH

The concentrate for injection has a pH adjusted to approximately 7.5.<sup>3398</sup>

## Trade Name(s)

Prevymis

## Administration

The entire contents of the intravenous bag containing the diluted solution of letermovir for infusion should be administered as an intravenous infusion at a constant rate over 1 hour through a peripheral catheter or central venous line.<sup>3398</sup> The drug should *not* be administered by intravenous bolus injection.<sup>3398</sup>

## Stability

Letermovir concentrate for injection is a clear, colorless solution that forms a clear solution ranging from colorless to yellow

upon dilution; variations in color within this range do not affect product quality.<sup>3398</sup> Intact vials should be stored at controlled room temperature in the original carton to protect from light.<sup>3398</sup>

Letermovir concentrate for injection should be visually inspected for particulate matter and discoloration in the vial and again once the solution has been diluted in the intravenous infusion bag; if visible particulates are present or if discoloration occurs, the solution should not be used and should be discarded.<sup>3398</sup> Vials are for single use only; any unused portion should be discarded.<sup>3398</sup>

## Sorption

Letermovir is noted to be compatible with polyvinyl chloride (PVC), ethylene vinyl acetate (EVA), and polyolefin (polypropylene and polyethylene) intravenous infusion bags, as well as PVC, polyethylene, polybutadiene, silicone rubber, styrene-butadiene copolymer, styrene-butadiene-styrene copolymer, and polystyrene infusion sets.<sup>3398</sup> Only intravenous infusion bags and infusion sets made of these materials are recommended for use with letermovir.<sup>3398</sup>

Letermovir also is compatible with radiopaque polyurethane catheters; however, the drug is not recommended for use with polyurethane-containing intravenous administration set tubing.<sup>3398</sup>

## Plasticizer Leaching

Letermovir is compatible with materials containing plasticizers such as diethylhexyl phthalate (DEHP), trioctyl trimellitate (TOTM), and benzyl butyl phthalate.<sup>3398</sup>

# Leucovorin Calcium

AHFS 92:12

## Products

Leucovorin calcium is available in lyophilized form in vials containing leucovorin 50, 100, 200, 350, and 500 mg as the calcium salt with sodium chloride and sodium hydroxide or hydrochloric acid to adjust the pH. Reconstitute the vials with bacteriostatic water for injection containing benzyl alcohol or sterile water for injection with the volumes indicated in Table 1.<sup>1(1/04) 4</sup>

**Table 1. Recommended reconstitution of leucovorin calcium<sup>1(1/04) 4</sup>**

Vial Size (mg)	Volume of Diluent (mL)	Concentration (mg/mL)
50	5	10
100	10	10
200	20	10
350	17.5	20
500	50	10

Leucovorin calcium is also available at a concentration of 10 mg/mL containing no preservative in vials of 10, 25, and 30 mL.<sup>4</sup>

## pH

From 6.5 to 8.5.<sup>17</sup>

## Compatibility Information

### Solution Compatibility

Dextrose 5%	MG <sup>b</sup>		910 mg	Under 10% loss in 24 hr at room temperature in light	1658	C
Dextrose 10%		LE	50 mg	Under 10% loss in 24 hr at room temperature in dark	488	C
Ringer's injection		LE	50 mg	Under 10% loss in 24 hr at room temperature in dark	488	C
Ringer's injection, lactated		LE	50 mg	Under 10% loss in 24 hr at room temperature in dark	488	C
Sodium chloride 0.9%	<sup>a</sup>	LE	1 and 1.5 g	Little loss in 4 days at 4 and 23°C in dark	1596	C

## Administration

Leucovorin calcium is administered by intramuscular or intravenous injection or infusion at a rate not exceeding 160 mg/min. When doses greater than 10 mg/m<sup>2</sup> are required, diluents containing benzyl alcohol should not be used for reconstitution.<sup>1(1/04) 4</sup>

## Stability

Leucovorin calcium injection should be stored at room temperature and protected from light.<sup>1(1/04) 4</sup>

The reconstituted solution of leucovorin calcium is stated to be stable for 7 days. When reconstituted with diluents that contain no preservatives, immediate use is recommended.<sup>1(1/04)</sup>

## pH Effects

Leucovorin calcium solutions exhibit good stability at pH 6.5 to 10. The pH of maximum stability was determined to be 7.1 to 7.4. Below pH 6, increased decomposition occurs.<sup>1276</sup>

## Central Venous Catheter

Leucovorin calcium (Gensia) 2 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

## Additional Compatibility Information

### *Fluorouracil*

Several articles reported the chemical stability and physical compatibility of fluorouracil with leucovorin calcium.<sup>505 980 1309 1387 1817</sup> However, more recent work found substantial amounts of subvisual particles in this drug combination over numerous concentrations when stored at 4, 23, and 32°C. Particulate formation sometimes clogged filters and disrupted multiple-day

treatment. Particulate formation began in about 24 hours in most samples, and particles were found in all samples within 7 days. Fluorouracil and leucovorin calcium in the same container can no longer be considered a compatible combination.<sup>1816</sup>

Fluorouracil combined with leucovorin calcium for repeated administration using a Fresenius implanted port resulted in blockage of the pump catheter and necessitated surgical removal of the port. The blockage was caused by precipitation of calcium carbonate in the catheter.<sup>2504</sup>

## Levetiracetam

AHFS 28:12.92

### Products

Levetiracetam is available as a 100-mg/mL concentrate for injection in 5-mL single-use vials.<sup>2833</sup> The concentrate must be diluted prior to administration.<sup>2833</sup>

Levetiracetam also is available as a single-use, ready-to-use solution for intravenous infusion containing 500 mg, 1 g, or 1.5 g levetiracetam in 100 mL of sodium chloride in dual-port plastic bags.<sup>2834</sup>

Both the concentrate and the ready-to-use formulations contain water for injection and sodium chloride as well as glacial acetic acid and sodium acetate trihydrate to adjust the pH.<sup>2833 2834</sup>

### pH

Approximately 5.5.<sup>2833 2834</sup>

### Osmolality

Levetiracetam 100-mg/mL concentrate for injection has an osmolality of approximately 950 mOsm/kg.<sup>2835</sup> Following dilution of 500 mg of the concentrate in 100 mL of sodium chloride 0.9%, the solution has an osmolality of approximately 430 mOsm/kg.<sup>2835</sup>

### Sodium Content

Ready-to-use solutions of levetiracetam 500 mg, 1 g, and 1.5 g in 100 mL of sodium chloride injection contain 820, 750, and 540 mg of sodium, respectively.<sup>2834</sup>

### Trade Name(s)

Keppra

### Administration

Levetiracetam concentrate for injection is administered by intravenous infusion over 15 minutes after dilution in 100 mL of

a compatible diluent.<sup>2833</sup> If a smaller infusion volume is required (e.g., for pediatric patients or fluid-restricted patients), the final concentration of the diluted solution should not exceed 15 mg/mL.<sup>2833</sup>

Single-use, ready-to-use solutions of levetiracetam should not be further diluted prior to intravenous infusion.<sup>2834</sup> The ready-to-use solution is administered by intravenous infusion over 15 minutes.<sup>2834</sup>

### Stability

Levetiracetam concentrate and diluted solutions should be clear and colorless.<sup>2833 2834</sup> Intact vials of levetiracetam concentrate and ready-to-use bags of levetiracetam in solution in their unopened aluminum overwrap should be stored at controlled room temperature.<sup>2833 2834</sup> Discolored products or products containing particulate matter should not be used.<sup>2833 2834</sup> Ready-to-use levetiracetam infusion bags should be used promptly once the aluminum overwrap has been removed.<sup>2834</sup>

The unused contents of an opened vial or a partially used infusion bag should be discarded.<sup>2833 2834</sup> Storage of levetiracetam diluted for infusion should not exceed 4 hours at 15 to 30°C.<sup>2835</sup>

### Syringes

Levetiracetam (Hospira) was diluted to a concentration of 40 mg/mL in sodium chloride 0.9% and packaged as 25 mL in 30-mL polypropylene syringes (Becton Dickinson).<sup>3114</sup> The syringes were stored for 14 days at 2 to 8°C.<sup>3114</sup> Neither changes in color or clarity nor appreciable changes in pH from baseline values occurred.<sup>3114</sup> Samples exhibited a loss of less than 6% of levetiracetam concentration at 14 days.<sup>3114</sup>

## Levocarnitine

AHFS 92:92

### Products

Levocarnitine is available as a 200-mg/mL solution in single-use (preservative-free) 5-mL vials containing 1 g of levocarnitine with hydrochloric acid or sodium hydroxide to adjust the pH in water for injection.<sup>3217 3218</sup>

### pH

The pH of the undiluted solution ranges from 6 to 6.5.<sup>3217 3218</sup>

### Trade Name(s)

Carnitor

### Administration

Levocarnitine is administered intravenously as a slow bolus injection over 2 to 3 minutes or by infusion.<sup>3217 3218</sup>

### Stability

Intact vials should be stored at controlled room temperature.<sup>3217 3218</sup> One manufacturer states that vials of the drug should be kept in the carton to protect from light until time of use and that vials should not be frozen.<sup>3218</sup>

Solutions should be visually inspected for particulate matter and discoloration prior to administration.<sup>3217 3218</sup> Any unused portion should be discarded.<sup>3217 3218</sup>

## Levofloxacin

AHFS 8:12.18

### Products

Levofloxacin is available as a 25-mg/mL preservative-free concentrate for injection in 20-mL (500-mg) and 30-mL (750-mg) single-use vials.<sup>2895</sup> This concentrate must be diluted to a 5-mg/mL solution before administration.<sup>2895</sup> Adding 250 mg (10 mL) to 40 mL of diluent, 500 mg (20 mL) to 80 mL of diluent, or 750 mg (30 mL) to 120 mL of diluent will result in a concentration of 5 mg/mL.<sup>2895</sup>

The drug is also available as premixed infusion solutions of 5 mg/mL in dextrose 5% in 50-mL (250-mg), 100-mL (500-mg), and 150-mL (750-mg) flexible plastic bags.<sup>2895</sup> The premixed infusion solutions in plastic bags are ready to use and require no further dilution.<sup>2895</sup> Sodium hydroxide and hydrochloric acid may have been added to adjust the pH.<sup>2895</sup>

### pH

From 3.8 to 5.8.<sup>2895</sup>

The pH of a 5-mg/mL solution in dextrose 5% or sodium chloride 0.9% is about 4.6 to 4.7.<sup>2895</sup> A 5-mg/mL solution had a pH of 4.9 in dextrose 5% in Ringer's injection, lactated, a pH of 5 in Plasma-Lyte 56/dextrose 5%, and a pH of 5.5 in sodium lactate 1/6 M.<sup>2895</sup>

### Tonicity

The premixed infusion solutions are nearly isotonic.<sup>2895</sup>

### Trade Name(s)

Levaquin

### Administration

The 25-mg/mL levofloxacin concentrate must be diluted to 5 mg/mL prior to administration.<sup>2895</sup> Levofloxacin is administered only at a concentration of 5 mg/mL by slow intravenous infusion over at least 60 minutes.<sup>2895</sup> Doses of 750 mg should be administered over 90 minutes.<sup>2895</sup> No other route is recommended.<sup>2895</sup> Rapid infusion or bolus administration must not be used because of the potential for hypotension.<sup>2895</sup>

### Stability

Intact vials should be stored at controlled room temperature and protected from light.<sup>2895</sup> The premixed infusion solutions

should be stored at or below 25°C and protected from light, freezing, and excessive heat.<sup>2895</sup> A brief exposure to temperatures up to 40°C does not adversely affect the premixed product.<sup>2895</sup> The injection and infusion admixtures are clear and yellow to greenish yellow in appearance.<sup>2895</sup> This color also does not adversely affect the product.<sup>1986 2895</sup> Discard any remaining unused portion of the injection because no preservatives are present.<sup>2895</sup>

Levofloxacin diluted in a compatible diluent to 5 mg/mL is stated to be stable for 72 hours stored at or below 25°C and for 14 days stored at 5°C.<sup>2895</sup>

Levofloxacin may form stable coordination compounds with metal ions.<sup>2895</sup> The chelation potential is greatest with Al<sup>3+</sup> and declines from Cu<sup>2+</sup> to Zn<sup>2+</sup> to Mg<sup>2+</sup> to Ca<sup>2+</sup>.<sup>2895</sup>

### pH Effects

Levofloxacin has a solubility of 100 mg/mL at pH values ranging from 0.6 to 5.8.<sup>2895</sup> The solubility increases as pH increases up to 6.7, with a maximum solubility of 272 mg/mL.<sup>2895</sup> Above pH 6.7, solubility decreases to a minimum of 50 mg/mL at pH 6.9.<sup>2895</sup>

### Freezing Solutions

Levofloxacin 5 mg/mL diluted in a compatible diluent in glass bottles or plastic infusion containers is stable for 6 months frozen at -20°C.<sup>2895</sup> Frozen solutions should be thawed at room temperature or in the refrigerator.<sup>2895</sup> Accelerated thawing using microwaves or hot water immersion is not recommended.<sup>2895</sup> Thawed solutions should not be refrozen.<sup>2895</sup>

### Light Effects

Levofloxacin undergoes slow degradation when exposed to ultraviolet light.<sup>2399</sup> Losses have been reported upon long-term light exposure.<sup>2636</sup>

### Central Venous Catheter

Levofloxacin (McNeil) 1 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

# Levoleucovorin Calcium

AHFS 92:12

## Products

Levoleucovorin calcium is available as a lyophilized powder in (preservative-free) single-use vials containing the equivalent of 50 or 175 mg of levoleucovorin.<sup>3196 3343</sup> The 50-mg vial also contains mannitol 50 mg and sodium hydroxide and/or hydrochloric acid to adjust the pH.<sup>3196</sup> The 50-mg vial should be reconstituted only with 5.3 mL of sodium chloride 0.9% to yield a levoleucovorin concentration of 10 mg/mL.<sup>3196</sup> The 175-mg vial also contains mannitol 175 mg and sodium hydroxide and/or hydrochloric acid to adjust the pH.<sup>3343</sup> The 175-mg vial should be reconstituted only with 17.7 mL of sodium chloride 0.9% to yield a levoleucovorin concentration of 10 mg/mL.<sup>3343</sup> Reconstitution with sodium chloride solutions containing a preservative (e.g., benzyl alcohol) has not been studied.<sup>3196 3343</sup> The reconstituted solution may be immediately diluted in sodium chloride 0.9% or dextrose 5% to a final levoleucovorin concentration of 0.5 to 5 mg/mL.<sup>3196 3343</sup>

Levoleucovorin calcium also is available as a solution in (preservative-free) single-use vials.<sup>3197</sup> Each 17.5- or 25-mL vial contains 175 or 250 mg, respectively, of levoleucovorin as the calcium salt in sodium chloride 0.83%.<sup>3197</sup> Each vial also contains sodium hydroxide to adjust the pH.<sup>3197</sup> Levoleucovorin calcium injection solution may be further diluted with sodium chloride 0.9% or dextrose 5% to a final concentration of 0.5 mg/mL.<sup>3197</sup>

## Equivalency

Levoleucovorin calcium pentahydrate 64 mg is equivalent to levoleucovorin 50 mg.<sup>3196</sup>

Levoleucovorin calcium pentahydrate 222 mg is equivalent to levoleucovorin 175 mg.<sup>3343</sup>

## pH

Levoleucovorin calcium injection solution has an adjusted pH ranging from 6.5 to 8.5.<sup>3197</sup>

## Compatibility Information

### Solution Compatibility

#### Levoleucovorin calcium

<sup>a</sup> Lyophilized formulation (175-mg) tested.

## Trade Name(s)

Fusilev

## Administration

Levoleucovorin calcium is administered intravenously by infusion or injection.<sup>3196 3197 3343</sup> For certain indications, the manufacturer states that the drug should be administered by slow intravenous injection over at least 3 minutes.<sup>3196</sup> Levoleucovorin calcium should *not* be administered at a rate faster than 160 mg/min due to the calcium content.<sup>3196 3197 3343</sup>

Levoleucovorin calcium should *not* be administered intrathecally.<sup>3196 3197 3343</sup>

## Stability

Intact vials of levoleucovorin calcium lyophilized powder for injection should be stored at controlled room temperature.<sup>3196 3343</sup> Intact vials of levoleucovorin calcium injection solution should be stored at 2 to 8°C.<sup>3197</sup> Both formulations should be stored in their cartons until use to protect from light.<sup>3196 3197 3343</sup>

Reconstituted and/or diluted solutions of levoleucovorin prepared with 50- or 175-mg vials of the lyophilized powder for injection and sodium chloride 0.9% may be stored at room temperature for up to 12 or 24 hours (total), respectively.<sup>3196 3343</sup> Diluted solutions of levoleucovorin prepared with 50- or 175-mg vials of the lyophilized powder for injection and dextrose 5% may be stored at room temperature for up to 4 hours.<sup>3196 3343</sup>

Diluted solutions of levoleucovorin prepared with the injection solution and sodium chloride 0.9% or dextrose 5% may be stored at room temperature for up to 4 hours.<sup>3197</sup>

Reconstituted and/or diluted solutions of levoleucovorin should be visually inspected for particulate matter and discoloration prior to administration; if cloudiness or precipitate is observed, solutions should not be used.<sup>3196 3197 3343</sup>

## Levothyroxine Sodium

AHFS 68:36.04

### Products

Levothyroxine sodium is available in 100-, 200-, and 500-mcg vials.<sup>2883</sup> Also present in the vials are dibasic sodium phosphate heptahydrate, mannitol, and sodium hydroxide.<sup>2883</sup> Reconstitute vials by adding 5 mL of sodium chloride 0.9%, resulting in solutions containing 20, 40, and 100 mcg/mL, respectively.<sup>2883</sup> Shake well to ensure complete dissolution.<sup>2883</sup>

### Administration

Levothyroxine sodium injection may be administered undiluted by intravenous injection.<sup>2883</sup> The drug also has been administered by intramuscular injection,<sup>2885</sup> however the current labeling no longer includes this information.<sup>2883</sup>

### Stability

Intact vials should be stored at controlled room temperature and protected from light.<sup>2883</sup> After reconstitution, the drug is stable for 4 hours; however, the manufacturer states that the drug should be used immediately.<sup>2883</sup> Vials are intended for

single-use only; unused portions should be discarded.<sup>2883</sup> The manufacturer also states that levothyroxine sodium injection should not be added to intravenous solutions.<sup>2883</sup>

### Syringes

Levothyroxine sodium 0.1 mg/mL in sodium chloride 0.9% was packaged as 5 mL in 6-mL polypropylene syringes (Monoject). No loss of drug was found after seven days at 5°C.<sup>2354</sup>

### Sorption

In a study of levothyroxine sodium stability in glass, polyolefin, and PVC containers for continuous infusion, delivery of the drug through PVC tubing resulted in 13% loss of drug in glass and polyolefin containers and 18% loss of drug in PVC containers over 1 hour as a result of sorption to the PVC materials.<sup>2884</sup> Levothyroxine sodium concentrations returned to greater than 90% of the initial concentration by 3 hours in all 3 container types and thereafter remained above 90% for the duration of the 24-hour study period.<sup>2884</sup> The use of polyolefin tubing or flushing of a PVC line with levothyroxine solution prior to administration has been suggested to minimize such sorption.<sup>2884</sup>

# Lidocaine Hydrochloride

AHFS 24:04.04.08

## Lignocaine Hydrochloride

### Products

Lidocaine hydrochloride for direct intravenous use is available in concentrations of 10 and 20 mg/mL in ampuls and vials from 5 to 50 mL and in 5-mL prefilled syringes. The drug also is available as 40-, 100-, and 200-mg/mL concentrates for intravenous admixture preparation. The pH of these solutions is adjusted with sodium hydroxide and/or hydrochloric acid. Multiple-dose vials and automatic injection devices also may contain methylparaben and EDTA or sulfites.<sup>4</sup>

Lidocaine hydrochloride also is available premixed in dextrose 5% in concentrations of 0.2, 0.4, and 0.8% (2, 4, and 8 mg/mL, respectively). The solutions are available in container sizes ranging from 250 to 1000 mL.<sup>4</sup>

### pH

The pH of the injection is about 6.5 but may range from 5 to 7.<sup>14</sup> The premixed infusion solutions in dextrose 5% have a pH of 3 to 7.<sup>4 17</sup>

### Osmolality

The osmolalities of lidocaine hydrochloride products were determined to be 296 mOsm/kg for the 10-mg/mL concentration and 352 mOsm/kg for the 20-mg/mL concentration.<sup>1233</sup>

### Osmolarity

The commercially available lidocaine hydrochloride 0.2, 0.4, and 0.8% premixed solutions have osmolarities of approximately 266, 281, and 308 mOsm/L, respectively.<sup>4</sup>

### Trade Name(s)

Xylocaine

### Administration

Lidocaine hydrochloride is administered by direct intravenous injection and continuous intravenous infusion.<sup>4</sup> The drug also may be administered by intramuscular injection.<sup>4 118 119 120</sup> Products containing 40, 100, or 200 mg/mL should not be administered by direct intravenous injection without prior dilution to a 1- or 2-mg/mL (0.1 or 0.2%) solution. Lidocaine hydrochloride products containing preservatives should not be given intravenously. Products containing epinephrine should not be used to treat arrhythmias.<sup>4</sup>

### Stability

Lidocaine hydrochloride injection and premixed infusion solutions should be stored at controlled room temperature and protected from excessive heat and freezing.<sup>4</sup>

### pH Effects

Although lidocaine hydrochloride is stable across a broad pH range, its pH of maximum stability is 3 to 6.<sup>1277</sup>

Buffering lidocaine hydrochloride injection with sodium bicarbonate has been used to reduce pain on injection. Increasing the pH results in an increased percentage of the drug being present as the unionized base, which is less stable and soluble. Lidocaine base precipitation has been shown to occur at a pH around 7.5 to 7.6.<sup>2409</sup>

The stability of lidocaine hydrochloride 2%, with and without epinephrine hydrochloride, was studied after alkalization with sodium bicarbonate. Lidocaine hydrochloride alone was alkalized to pH 7.2, while the lidocaine–epinephrine combination was adjusted to pH 6.5 and also 7.05. The combinations were compatible, and no loss of lidocaine or epinephrine occurred over 6 hours.<sup>1401</sup>

The stability of lidocaine hydrochloride 1% (Elkins-Sinn) buffered with sodium bicarbonate to pH 6.8, 7.2, and 7.4 was evaluated. No loss occurred in 27 days at pH 6.8. At pH 7.2, adequate concentrations were retained for 19 days, but by 27 days, concentrations had fallen to about 88% and a crystalline precipitate formed. At pH 7.4, losses of up to 23% were accompanied by crystalline precipitation between 5 and 15 days.<sup>2407</sup>

Lidocaine hydrochloride is stable when mixed with certain acid-stable drugs such as epinephrine hydrochloride, norepinephrine bitartrate, and isoproterenol hydrochloride. However, its buffering action may raise the pH of intravenous admixtures above 5.5, the maximum pH for stability of the other drugs. The final pH is usually about 6. These drugs begin to deteriorate within several hours. Note: This does not apply to commercial lidocaine–epinephrine combinations, which have the pH adjusted to retain epinephrine.<sup>24</sup>

### Syringes

Lidocaine hydrochloride (Abbott) 20 mg/mL was packaged as 10 mL of undiluted injection in 12-mL polypropylene syringes (Becton Dickinson) and stored at 23°C under fluorescent light and 4°C. No lidocaine loss was found after 90 days of storage.<sup>2428</sup>

Lidocaine hydrochloride 2% (20 mg/mL) in auto-injector syringes (Abbott) was evaluated for stability over 45 days under use conditions in paramedic vehicles. Temperatures fluctuated with locations and conditions and ranged from 6.5°C (43.7 °F) to 52°C (125.6 °F) in high desert conditions. No visually apparent changes occurred, and no loss was found.<sup>2548</sup>

Lidocaine hydrochloride under simulated summer conditions in paramedic vehicles was exposed to temperatures ranging from 26 to 38°C over 4 weeks. No loss of the drug occurred.<sup>2562</sup>

### Sorption

Lidocaine hydrochloride in solutions with acidic pH was shown not to exhibit sorption to polyvinyl chloride (PVC) bags and tubing, elastomeric pump reservoirs, polyethylene tubing, Silastic tubing, and polypropylene syringes.<sup>12 536 606 2014</sup>

However, in a slightly alkaline (pH 8) cardioplegia solution, the percentage of unionized lidocaine base increased to 58%. This compares to 3% in dextrose 5% and sodium chloride 0.9% at around pH 6. The unionized form is highly lipid soluble and may interact with PVC bags. Storage of the cardioplegia solutions in PVC bags at 22°C resulted in a 12 to 19% lidocaine loss in 2 days and a 65 to 75% loss in 21 days. Degradation was not likely because storage in glass bottles did not result in any lidocaine loss after 21 days at 22°C. Refrigeration of the PVC bags at 4°C slowed the lidocaine loss to 9% or less in 21 days.<sup>776</sup>

### Filtration

Lidocaine hydrochloride (Astra) 200 mg/L in dextrose 5% and sodium chloride 0.9% did not display significant sorption to a

0.45- $\mu$ m cellulose membrane filter (Abbott S-A-I-F) during an 8-hour simulated infusion.<sup>567</sup>

### Central Venous Catheter

Lidocaine hydrochloride (Astra) 2 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Lincomycin Hydrochloride

AHFS 8:12.28.20

### Products

Lincomycin hydrochloride is available in 2- and 10-mL vials.<sup>3164 3165</sup> Each mL contains lincomycin hydrochloride equivalent to lincomycin 300 mg and benzyl alcohol 9.45 mg.<sup>3164 3165</sup>

### pH

From 3 to 5.5.<sup>17</sup>

### Trade Name(s)

Lincocin

### Administration

Lincomycin hydrochloride may be administered by intramuscular injection, intravenous infusion, or subconjunctival

injection.<sup>3164 3165</sup> For intravenous infusion, each gram of lincomycin should be diluted in at least 100 mL of a compatible infusion solution and infused over at least 1 hour at a rate of 1 g per hour.<sup>3164 3165</sup>

### Stability

Lincomycin hydrochloride injection should be stored at controlled room temperature.<sup>3164 3165</sup>

### pH Effects

The degradation rate for lincomycin hydrochloride was reported to be at a minimum near pH 4; the drug was least stable at pH 2.<sup>3166</sup>

## Compatibility Information

## Linezolid

AHFS 8:12.28.24

### Products

Linezolid is available as a single-use, ready-to-use solution for infusion in 100-, 200-, and 300-mL flexible plastic containers.<sup>3183</sup>  
<sup>3184</sup> Each mL of linezolid (Zyvox, Pfizer) ready-to-use solution for infusion provides linezolid 2 mg along with dextrose, sodium citrate, and citric acid in water for injection.<sup>3183</sup> Each mL of linezolid (Hospira) ready-to-use solution for infusion provides linezolid 2 mg along with citric acid anhydrous, sodium chloride, and sodium hydroxide in water for injection.<sup>3184</sup> Sodium hydroxide and/or hydrochloric acid is used to adjust the pH.<sup>3183 3184</sup>

### Tonicity

Linezolid ready-to-use solutions for infusion are isotonic.<sup>3183 3184</sup>

### pH

Linezolid (Zyvox) ready-to-use solution for infusion is adjusted to pH 4.8.<sup>3183</sup>

Linezolid (Hospira) ready-to-use solution for infusion is adjusted to pH 4.4 to 5.2.<sup>3184</sup>

### Sodium Content

The sodium concentration of linezolid (Zyvox) ready-to-use solution for infusion is 0.38 mg/mL or 1.7 mEq in a 100-mL bag, 3.3 mEq in a 200-mL bag, and 5 mEq in a 300-mL bag.<sup>3183</sup>

The sodium concentration of linezolid (Hospira) ready-to-use solution for infusion is 3.98 mg/mL or 52 mEq in a 300-mL bag.<sup>3184</sup>

### Trade Name(s)

Zyvox

## Compatibility Information

### Solution Compatibility

#### Linezolid

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 5%	BRN		2 g	Little to no loss in 34 days at 25°C	3514	C
Dextrose 10%			2 g	Little to no loss in 34 days at 25°C	3514	C
Sodium chloride 0.9%	BA		2 g	Little to no loss in 34 days at 25°C	3514	C

### Administration

Linezolid is administered by intravenous infusion over a period of 30 to 120 minutes.<sup>3183 3184</sup> If a common intravenous line is being used to administer other drugs in addition to linezolid, the line should be flushed with a compatible infusion solution (e.g., sodium chloride 0.9%, dextrose 5%, Ringer's injection, lactated) prior to and following infusion of linezolid.<sup>3183 3184</sup>

### Stability

Linezolid solutions may exhibit a yellow color that can intensify over time without affecting the stability of the drug.<sup>3183 3184</sup> Intact containers should be kept in their protective overwrap until ready for use, and should be stored at controlled room temperature and protected from light and freezing.<sup>3183 3184</sup>

Linezolid solutions should be visually inspected for particulate matter prior to administration.<sup>3183 3184</sup> The manufacturers state that additives should not be mixed with linezolid ready-to-use solution for infusion.<sup>3183 3184</sup>

### Temperature Effects

Linezolid (Pfizer) 2 mg/mL remained stable without noticeable degradation for 72 hours when stored at 70°C.<sup>3514</sup>

### Sorption

Linezolid was found to be compatible with common types of intravenous administration sets including diethylhexyl phthalate (DEHP) plasticized PVC, trioctyl trimellitate (TOTM) plasticized PVC, and polyolefin sets. The total dose of linezolid was fully delivered with the delivered concentration remaining constant throughout. In addition, no detectable levels of plasticizer were found in the delivered solutions.<sup>2338</sup>

## Additive Compatibility

### Linezolid

Test Drug	Mfr	Conc/L or %	Mfr	Conc/L or %	Test Solution	Remarks	Ref	C/I
Aztreonam	SQ	20 g	PHU	2 g	<sup>a</sup>	Physically compatible with no linezolid loss in 7 days at 4 and 23°C protected from light. About 9% aztreonam loss at 23°C and less than 4% loss at 4°C in 7 days	2263	C
Cefazolin sodium	APC	10 g	PHU	2 g	<sup>a</sup>	Physically compatible with 5% or less loss of each drug in 3 days at 23°C and 7 days at 4°C protected from light	2262	C
Ceftazidime	GW	20 g	PHU	2 g	<sup>a</sup>	Physically compatible with no linezolid loss in 7 days at 4 and 23°C protected from light. Ceftazidime losses of 5% in 24 hr and 12% in 3 days at 23°C and about 3% in 7 days at 4°C	2262	C
Ceftriaxone sodium	RC	10 g	PHU	2 g	<sup>a</sup>	Physically compatible, but up to 37% ceftriaxone loss in 24 hr at 23°C and 10% loss in 3 days at 4°C	2262	I
Ceftriaxone sodium			PHU, HOS			Stated to be chemically incompatible	3183, 3184	I
Ciprofloxacin	BAY	4 g	PHU	2 g	<sup>a</sup>	Physically compatible with little or no loss of either drug in 7 days at 23°C protected from light. Refrigeration results in precipitation after 1 day	2334	C
Erythromycin lactobionate	AB	5 g	PHU	2 g	<sup>a</sup>	Erythromycin loss of 15% in 1 hr and 30% in 4 hr at 23°C. Loss of 45% in 1 day at 4°C	2333	I
Gentamicin sulfate	AB	800 mg	PHU	2 g	<sup>a</sup>	Physically compatible. Little linezolid loss in 7 days at 4 and 23°C in dark. Gentamicin losses of 5 to 7% in 7 days at 4°C and 8% in 5 days at 23°C	2332	C
Levofloxacin	OMN	5 g	PHU	2 g	<sup>a</sup>	Physically compatible. Little drug loss in 7 days at 4 and 23°C in dark	2334	C
Tobramycin sulfate	GNS	800 mg	PHU	2 g	<sup>a</sup>	Physically compatible. Little linezolid loss in 7 days at 4 and 23°C in dark. No tobramycin loss in 7 days at 4°C but losses of 4% in 1 day and 12% in 3 days at 23°C	2332	C
Trimethoprim–sulfamethoxazole	ES	800 mg <sup>b</sup>	PHU	2 g	<sup>a</sup>	A large amount of white needle-like crystals forms immediately	2333	I

<sup>a</sup> Admixed in the linezolid infusion container.

<sup>b</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>d</sup> Ampicillin component. Ampicillin in a 2:1 fixed-ratio concentration with sulbactam.

<sup>e</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>f</sup> Not specified whether concentration refers to single component or combined components.

<sup>g</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>h</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>i</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>j</sup> Ceftazidime component. Ceftazidime in a 4:1 fixed-ratio concentration with avibactam.

<sup>k</sup> Tested in both dextrose 5% and Ringer's injection, lactated.

<sup>l</sup> Tested as the premixed infusion solution.

**Additional Compatibility Information****Infusion Solutions**

The manufacturers state that linezolid ready-to-use solutions for infusion are compatible with sodium chloride 0.9%, dextrose 5%, and Ringer's injection, lactated.<sup>3183 3184</sup>

One study found little to no loss of linezolid in Hartmann's solution in 34 days at 25°C.<sup>3514</sup>

**Peritoneal Dialysis Solutions**

Linezolid 150, 300, and 600 mg/L in Dianeal PD-2 with 1.5 or 4.25% dextrose stored at 37, 25, and 4°C protected from light was physically compatible and exhibited no loss.<sup>2500</sup>

## Lorazepam

### AHFS 28:24.08

#### Products

Lorazepam is available in 2- and 4-mg/mL solutions in 1-mL single-use vials and 10-mL multidose vials.<sup>3031</sup> Both concentrations also are available in 1-mL disposable syringe cartridges.<sup>3033</sup> Each mL of lorazepam injection solution also contains 0.18 mL of polyethylene glycol 400 and 2% benzyl alcohol in propylene glycol.<sup>3031 3033</sup>

For intramuscular use, lorazepam may be injected undiluted.<sup>3031 3033</sup> For intravenous use, however, lorazepam *must* be diluted immediately prior to injection with an equal volume of a compatible diluent (e.g., sterile water for injection, dextrose 5%).<sup>3031 3033</sup>

To dilute the dose in a syringe cartridge, all of the air should first be eliminated and the proper volume of a compatible diluent (e.g., sterile water for injection, dextrose 5%) should then be aspirated.<sup>3033</sup> The plunger should then be pulled back slightly to provide some mixing space and the syringe cartridge should be repeatedly and gently inverted to mix the contents.<sup>3033</sup> A similar procedure should be followed for diluting a dose withdrawn from a vial, taking care to repeatedly and gently invert the container until a homogenous solution results.<sup>3031</sup> To avoid air entrapment, neither the syringe cartridge nor the container should be shaken vigorously.<sup>3031 3033</sup>

#### Trade Name(s)

Ativan

#### Administration

Lorazepam may be administered by deep intramuscular injection; alternatively, the drug may be administered by intravenous injection, when diluted immediately prior to use with an equal volume of a compatible diluent (e.g., sterile water for injection, dextrose 5%);<sup>3031 3033</sup> the volume of the diluent to be added should not exceed the volume of the drug.<sup>3033</sup> Intravenous injection should be made slowly (i.e., at a rate not exceeding 2 mg/min), with frequent aspiration, directly into a vein or into the tubing of a running intravenous infusion.<sup>3031 3033</sup>

Lorazepam also has been administered by continuous intravenous infusion.<sup>3034</sup>

Care should be taken to ensure that intra-arterial administration or perivascular extravasation do not occur.<sup>3031 3033</sup>

#### Stability

Intact vials and syringe cartridges of lorazepam should be refrigerated and stored in the original carton to protect from light.<sup>3031 3033</sup> One manufacturer had previously stated that the product could be stored for up to 2 weeks at room temperature<sup>1181</sup> and

other manufacturers had acknowledged that both physical and chemical stability were acceptable for 60 to 90 days at room temperature;<sup>1674 2829</sup> however, these recommendations for extended room temperature stability are no longer supported by manufacturers.<sup>3032</sup>

Lorazepam injection solution should be visually inspected for discoloration and particulate matter; if discolored or if a precipitate is present, the solution should not be used.<sup>3031 3033</sup>

#### Precipitation

The choice of commercial lorazepam concentration to use in the preparation of dilutions is a critical factor in the physical stability of the dilutions.<sup>2207 2208</sup> Both the 2- and 4-mg/mL concentrations utilize the same concentrations of solubilizing solvents.<sup>1945 1981 2207 3031 3033</sup> On admixture, the solvents that keep the aqueous insoluble lorazepam in solution are diluted twice as much using the 4-mg/mL concentration than if the 2-mg/mL were used, resulting in different precipitation potentials for the same concentration of lorazepam.<sup>1945 1981 2207</sup> Care should be taken to ensure that the compounding procedure that is to be used for lorazepam admixtures has been demonstrated to result in solutions in which the lorazepam remains soluble.

Lorazepam concentrations up to 0.08 mg/mL have been reported to be physically stable, while occasional precipitate formation in admixtures of lorazepam 0.1 to 0.2 mg/mL has been reported. The precipitate has been observed in both containers and in administration set tubing.<sup>1943 1979 1980</sup> In one case, a visible precipitate formed in a lorazepam 0.5-mg/mL admixture in sodium chloride 0.9% in a glass bottle.<sup>1945</sup> However, a 0.5-mg/mL concentration may remain in solution longer if prepared from the 2-mg/mL concentration, yielding a higher concentration of organic solvents in the final admixture.<sup>1981 2207</sup> Concentrations of 1 and 2 mg/mL have been reported to be physically stable for up to 24 hours, as well as concentrations below 0.08 mg/mL.<sup>1980 2208</sup> Concentrations in the middle range of 0.08 to 1 mg/mL may be problematic.<sup>1980</sup> In one report, use of lorazepam 2 mg/mL to prepare lorazepam 1-mg/mL admixtures in dextrose 5% or sodium chloride 0.9% was acceptable, but use of the lorazepam 4-mg/mL concentration to prepare the same solutions resulted in almost immediate precipitation.<sup>2207</sup>

Lorazepam solubility in common infusion solutions has been reported (Table 1). Solubility of lorazepam in sodium chloride 0.9% is approximately half that found in the other tested solutions. This result was attributed to the pH of the sodium chloride 0.9% solution (pH 6.3) being essentially the same as the isoelectric point of lorazepam (pH 6.4), where aqueous solubility would be the lowest. Dextrose 5% was the best diluent for lorazepam in this study.<sup>787</sup>

**Table 1. Lorazepam equilibrium solubility<sup>787</sup>**

Solution	Lorazepam Solubility (mg/mL)	Solution pH
Deionized water	0.054	7.09
Dextrose 5%	0.062	4.41
Ringer's injection, lactated	0.055	7.21
Sodium chloride 0.9%	0.027	6.30

### Bacteriostatic Water

Dilution of lorazepam (Wyeth) to 1 mg/mL with bacteriostatic water for injection (bacteriostat unspecified), packaged in glass vials, resulted in lorazepam losses. Losses of about 10% at 4°C and 12% at 22°C occurred in 7 days. Drug precipitated in varying periods after the first week of storage.<sup>1840</sup>

### Syringes

Lorazepam (Wyeth) 2 mg/mL was packaged as 3 mL in 10-mL polypropylene infusion pump syringes (Pharmacia Deltec). About 12 to 14% loss occurred in 3 days and 25% loss occurred in 10 days at 5 and 30°C. The authors recommended against storing lorazepam in the syringes for these time periods.<sup>1967</sup>

Lorazepam (Wyeth) 1 mg/mL, prepared from the 2-mg/mL commercial concentration and diluted in dextrose 5% or in sodium chloride 0.9%, was filled as 40 mL in 60-mL polypropylene syringes (Becton Dickinson). The filled syringes were stored at 22°C for 28 hours. Visual inspection found that the solutions remained physically stable, and less than 3% drug loss occurred in this time period.<sup>2208</sup>

The physical and chemical stability of lorazepam (Wyeth-Ayerst) 0.2, 0.5, and 1 mg/mL in dextrose 5% and in sodium chloride 0.9% was evaluated when packaged in polypropylene syringes. When prepared using lorazepam 2 mg/mL, the solutions were found to be physically stable over 24 hours and chemically stable for 48 hours at room temperature. When

prepared using lorazepam 4 mg/mL, the solutions consistently precipitated.<sup>2416</sup>

Lorazepam (Pfizer) 4 mg/24 mL in sodium chloride 0.9% in a 30-mL polypropylene syringe (BD) was physically stable for 48 hours at room temperature.<sup>3545</sup>

### Sorption

Lorazepam (Wyeth) 2- and 4-mg/mL concentrations were diluted 1:1 using dextrose 5%, sodium chloride 0.9%, and water for injection. A 2-mL sample of each dilution was injected into the Y-sites of administration sets from 5 different manufacturers through which dextrose 5%, sodium chloride 0.9%, Ringer's injection, or Ringer's injection, lactated was flowing at rates of 30 and 125 mL/hr. No differences were found among the various infusion sets, infusion solutions, or flow rates. All effluent solutions were visually acceptable and had no loss of lorazepam.<sup>786</sup>

In another study, lorazepam (Wyeth) 2 mg/50 mL in dextrose 5% was delivered at rates of 600, 200, and 100 mL/hr using an infusion controller fitted with 180 or 350 cm of polyvinyl chloride (PVC) tubing. Lorazepam loss due to sorption was greater with the longer tubing and at slower rates. Losses ranged from a high of 5% (350 cm, 100 mL/hr) to a low of 0.7% (180 cm, 600 mL/hr).<sup>787</sup>

In static sorption studies, lorazepam (Wyeth) 2 mg/50 mL in dextrose 5% was filled into PVC containers in the following amounts: 50 mL into 50-mL bags, 100 mL into 50-mL bags, and 100 mL into 250-mL bags. The bags were stored at 23°C. A rapid initial loss of lorazepam occurred (about 3.9 to 5.8% in the first hour) followed by a slower, approximately constant loss after 8 hours. Cumulative losses of 6 to 8% occurred in about 5 hours in the smaller bags with smaller bag surface area to volume ratios. The solution in the larger bags exhibited over a 10% loss in 2 hours.<sup>787</sup>

### Plasticizer Leaching

Lorazepam (Wyeth-Ayerst) 0.1 mg/mL in dextrose 5% did not leach diethylhexyl phthalate (DEHP) plasticizer from 50-mL PVC bags in 24 hours at 24°C.<sup>1683</sup>

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>d</sup> Tested in bacteriostatic sodium chloride 0.9% preserved with benzyl alcohol 0.9%.

<sup>e</sup> Tested in Ringer's injection, lactated.

<sup>f</sup> Lyophilized formulation tested.

<sup>g</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>h</sup> Concentration expressed in milligrams of phenytoin sodium equivalents (PE) per mL.

<sup>i</sup> Amoxicillin component. Amoxicillin in a 10:1 fixed-ratio concentration with clavulanic acid.

<sup>j</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>k</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>l</sup> Not specified whether concentration refers to single component or combined components.

<sup>m</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>n</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>o</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>p</sup> Test performed using the formulation WITH edetate disodium.

## Magnesium Sulfate

AHFS 28:12.92

### Products

Magnesium sulfate is available in concentrations of 50, 8, 4, 2, and 1% in a variety of container sizes.<sup>4</sup> The 50% solution provides 500 mg/mL of magnesium sulfate (magnesium 4.06 mEq/mL). The pH of these concentrations may have been adjusted with sodium hydroxide and/or sulfuric acid.<sup>1(7/07) 4</sup>

Magnesium sulfate is available as 4% (40 mg/mL; 0.325 mEq/mL) and 8% (80 mg/mL; 0.65 mEq/mL) solutions in water for injection. Magnesium sulfate in dextrose 5% is available as 1% (10 mg/mL; 0.081 mEq/mL) and 2% (20 mg/mL; 0.162 mEq/mL).<sup>1(7/07)</sup>

### pH

Magnesium sulfate injection has a pH adjusted to 5.5 to 7.<sup>1(7/07)</sup> The premixed infusion solutions have pH values in the range of 3.5 to 6.5.<sup>17</sup>

### Osmolarity

The 50% solution has a calculated osmolarity of 4060 mOsm/L.<sup>1(7/07)</sup>

Magnesium sulfate 4 and 8% solutions in water for injection have osmolarities of 325 and 649 mOsm/L, respectively. Magnesium sulfate 1 and 2% solutions in dextrose 5% have osmolarities of 333 and 415 mOsm/L.<sup>1(7/07)</sup>

### Administration

Magnesium sulfate may be administered by intramuscular or direct intravenous injection and by continuous or intermittent intravenous infusion. For intravenous injection, a concentration of 20% or less should be used; the rate of injection should not exceed 1.5 mL of a 10% solution (or equivalent) per minute. For intramuscular injection, a 25 or 50% concentration is satisfactory for adults, but dilute to 20% for infants and children.<sup>1(7/07) 4</sup>

### Stability

Magnesium sulfate 50% injection and magnesium sulfate 4 and 8% in water for injection or 1 and 2% in dextrose 5% should be stored at controlled room temperature and protected from freezing.<sup>1(7/07) 4</sup> Refrigeration of intact ampuls may result in precipitation or crystallization.<sup>593</sup>

## Compatibility Information

### Solution Compatibility

#### Magnesium sulfate

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 5%	MG	AB	40 g	Physically compatible. Stable for 60 days at 0°C	922	C
Ringer's injection, lactated	BA <sup>a b</sup>	AMR	37 g	Visually compatible. No change in composition in 3 months stored at room temperature	2184	C
Sodium chloride 0.9%	BA <sup>a b</sup>	AMR	37 g	Visually compatible. No change in composition in 3 months stored at room temperature	2184	C

<sup>a</sup> Tested in glass containers.

<sup>b</sup> Tested in PVC containers.

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>d</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>e</sup> Tested in dextrose 5% in Ringer's injection, dextrose 5% in Ringer's injection, lactated, dextrose 5%, Ringer's injection, lactated, and sodium chloride 0.9%.

<sup>f</sup> Tested in Ringer's injection, lactated.

<sup>g</sup> Extemporaneously prepared product.

<sup>h</sup> Lyophilized formulation tested.

<sup>i</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>j</sup> Tested in dextrose 5% in sodium chloride 0.225%.

<sup>k</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>l</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>m</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>n</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>o</sup> Ceftazidime component. Ceftazidime in a 4:1 fixed-ratio concentration with avibactam.

<sup>p</sup> Tested in dextrose 5%, sodium chloride 0.9%, and Ringer's injection, lactated.

<sup>q</sup> Test performed using the formulation WITH edetate disodium.

# Mannitol

## AHFS 40:28.12

### Products

Mannitol is available in concentrations ranging from 5 to 25%.<sup>1(6/06) 4</sup>

Concentration	Osmolarity	Available Sizes
5%	275 mOsm/L	1000 mL
10%	550 mOsm/L	500 and 1000 mL
15%	825 mOsm/L	500 mL
20%	1100 mOsm/L	250 and 500 mL
25%	1375 mOsm/L	50 mL

### pH

From 4.5 to 7.<sup>1(6/06) 4</sup>

### Trade Name(s)

Osmitrol

### Administration

Mannitol is administered by intravenous infusion. An administration set with a filter should be used for infusion solutions containing mannitol 20% or more. The dosage, concentration, and administration rate are dependent on the patient's condition and response.<sup>1(6/06) 4</sup>

### Stability

Mannitol solutions should be stored at controlled room temperature and protected from freezing.<sup>1(6/06) 4</sup> The solutions are chemically stable. Mannitol 25% was chemically and physically stable after 5 autoclavings at 250°F for 15 minutes. In addition, no extracts or visible particles from the rubber closures were found.<sup>83</sup>

### Crystallization

In concentrations of 15% or greater, mannitol may crystallize when exposed to low temperatures.<sup>1(6/06) 4 593</sup> Do not use a mannitol solu-

tion containing crystals. If such crystallization occurs, the recommended procedure for resolubilization is to heat the mannitol in a dry heat cabinet to 70°C for flexible plastic containers with the overwrap intact or to 80°C for glass containers with vigorous shaking. The use of a water bath is not recommended. Mannitol 25% in glass vials may be autoclaved at 121°C. The solution should cool to body temperature before use.<sup>1(6/06) 4</sup>

The use of a microwave oven to resolubilize crystallized mannitol in glass ampuls has been suggested. Exposure to microwave radiation followed by shaking satisfactorily resolubilized the crystals in a shorter total time than the water bath and autoclave methods and resulted in no chemical decomposition.<sup>694</sup>

Unfortunately, the use of microwave radiation to solubilize mannitol crystals is a highly risky undertaking. Explosions of mannitol ampuls during microwave exposure have been reported.<sup>695 697</sup> Such explosions could injure someone as well as ruin the microwave oven. The explosion results from pressure building during the heating of the solution that occurs from the microwave exposure.<sup>696 697</sup>

One inventive pharmacist redissolved mannitol crystals using a coffeemaker.<sup>1114</sup>

As an alternative to resolubilizing techniques, the use of warming chambers to maintain the solutions in a crystal-free condition has been recommended.<sup>698 699 700</sup> Various chambers have been described, including a wooden cabinet,<sup>698</sup> a metal kettle,<sup>699</sup> and even a bun warmer.<sup>700</sup> Storage temperatures of 35 and 50°C have been utilized.<sup>698 699</sup>

A related but differing effect is seen when supersaturated solutions of mannitol are placed in polyvinyl chloride (PVC) bags. Within a few minutes, a heavy white flocculent precipitate forms. The needle-like crystals in mannitol solutions result from slow undisturbed growth. The white flocculent mannitol precipitate results from contact with the PVC surfaces, which act as nuclei for rapid crystallization of small crystals. Attempts to resolubilize the precipitate with the aid of heat are not fruitful because crystallization may recur in a short time.<sup>432</sup>

# Mechlorethamine Hydrochloride

AHFS 10:00

Mustine Hydrochloride

## Products

Mechlorethamine hydrochloride is available in vials containing 10 mg of drug and sodium chloride qs 100 mg. While taking appropriate protective measures, including wearing protective gloves, reconstitute the vial with 10 mL of water for injection or sodium chloride 0.9%. With the needle in the rubber stopper, shake the vial several times to dissolve the drug. The resultant solution contains mechlorethamine hydrochloride 1 mg/mL.<sup>1(10/05)</sup>

## pH

The reconstituted solution has a pH of 3 to 5.<sup>1(10/05) 4</sup>

## Trade Name(s)

Mustargen

## Administration

Mechlorethamine hydrochloride is administered intravenously or into body cavities.<sup>1(10/05) 4</sup> The drug is extremely irritating to tissues and should not be given intramuscularly or subcutaneously.<sup>4</sup> For intravenous use, the drug may be injected over a few minutes directly into the vein or into the tubing of a running infusion solution.<sup>1(10/05) 4</sup> After administration, flushing the vein with about 5 to 10 mL of intravenous solution has been recommended.<sup>4</sup> The drug is a powerful vesicant, and extravasation should be avoided.<sup>1(10/05) 4 377</sup> For intracavitary administration, the drug may be diluted up to 100 mL with sodium chloride 0.9%.<sup>1(10/05) 4</sup>

Spillage of the drug on gloves, etc., can be neutralized by soaking in an aqueous solution containing equal amounts of sodium thiosulfate 5% and sodium bicarbonate 5% for 45 minutes. Unused injection solution also may be neutralized by mixing with an equal volume of the sodium thiosulfate–sodium bicarbonate solution for 45 minutes.<sup>1(10/05) 1200</sup>

## Stability

In dry form, the drug is a light yellow-brown and is stable at temperatures up to 40°C.<sup>4</sup> Solutions decompose on standing and should be prepared immediately before use. The drug is even less stable in neutral or alkaline solutions than in the acidic reconstituted solution. Do not use if the solution is discolored or if water droplets form within the vial before reconstitution. Discard unused portions after neutralization.<sup>1(10/05) 4</sup>

Because of the rapid decomposition of mechlorethamine hydrochloride in solution, administration in intravenous infusion solutions is not recommended.<sup>4</sup> One report indicated a 7% loss of mechlorethamine in one hour at room temperature when diluted to 0.1 mg/mL in sodium chloride 0.9%.<sup>923</sup> Injecting the drug into the tubing of a running intravenous infusion rather than adding it to the entire volume of the solution minimizes the extent of chemical decomposition.<sup>1(10/05)</sup>

The stability of mechlorethamine hydrochloride (Boots) 1 mg/mL when reconstituted with water for injection or sodium chloride 0.9% in vials and plastic syringes was determined. About an 8 to 10% loss occurred in samples over six hours at 22°C; losses of 4 to 6% occurred in six hours in samples stored at 4°C.<sup>1279</sup>

Immersion of a needle with an aluminum component in mechlorethamine (MSD) 1 mg/mL resulted in no visually apparent reaction after seven days at 24°C.<sup>988</sup>

## Freezing Solutions

The stability of mechlorethamine hydrochloride (Boots) 1 mg/mL in water for injection and sodium chloride 0.9% frozen at –20°C was determined. In water for injection, about a 7% loss occurred after 12 weeks; about a 15% loss occurred in eight weeks with sodium chloride 0.9% as the diluent. At a concentration of 10 mg/500 mL in sodium chloride 0.9% in PVC bags, about a 10% loss occurred in eight weeks frozen at –20°C.<sup>1279</sup>

## Meloxicam

AHFS 28:08.04.92

### Products

Meloxicam injection is available as an opaque, pale yellow dispersion in 2-mL single-dose vials containing 1 mL of the dispersion.<sup>3552</sup> Each mL of the dispersion contains 30 mg of meloxicam, as well as sucrose 60 mg, polyvinylpyrrolidone 9 mg, and sodium deoxycholate 3 mg in water for injection.<sup>3552</sup>

### Trade Name(s)

Anjeso

### Administration

Meloxicam is for intravenous use only.<sup>3552</sup> The drug should be administered as a direct intravenous injection over 15 seconds.<sup>3552</sup>

### Stability

Meloxicam injection is an opaque, pale yellow aqueous dispersion.<sup>3552</sup> Intact vials of the drug should be stored at 15 to 25°C, with excursions permitted from 4 to 30°C.<sup>3552</sup> Vials should be stored in the carton to protect from light.<sup>3552</sup> Freezing should be avoided.<sup>3552</sup>

© Copyright, July 2020. American Society of Health-System Pharmacists, Inc.

# Melphalan Hydrochloride

## AHFS 10:00

### Products

Melphalan hydrochloride (generic versions of Alkeran, which is no longer commercially available in the US) is available as a lyophilized powder in single-use or single-dose vials containing the equivalent of 50 mg of melphalan and povidone 20 mg.<sup>3173</sup>  
<sup>3425 3426</sup> Each vial is packaged with a 10-mL vial of special diluent containing sodium citrate 0.2 g, propylene glycol 6 mL, alcohol (e.g., ethanol [96%] 0.52 mL,<sup>3173</sup> dehydrated alcohol 0.51 mL,<sup>3425</sup> ethanol [100%] 0.5 mL),<sup>3426</sup> and sterile water for injection.<sup>3173</sup>  
<sup>3425 3426</sup> The contents of each vial should be reconstituted by rapidly injecting 10 mL of the special diluent into the vial using a syringe with a 20-gauge or larger needle, and the vial should be shaken vigorously until the solution is clear to yield a 5-mg/mL solution of melphalan; rapid addition of the diluent and subsequent vigorous shaking are important for proper dissolution of the drug.<sup>3173 3425 3426</sup> The appropriate dose of the reconstituted solution should be diluted immediately in sodium chloride 0.9% to a concentration not exceeding 0.45 mg/mL.<sup>3173 3425 3426</sup>

Melphalan hydrochloride (Evomela, Spectrum) also is available as a lyophilized powder in single-dose vials containing the equivalent of 50 mg of melphalan and betadex sulfobutyl ether sodium 2700 mg as a stabilizing excipient.<sup>3171 3172</sup> This formulation is propylene glycol-free.<sup>3171 3172 3427</sup> The contents of each vial should be reconstituted with 8.6 mL of sodium chloride 0.9% to yield a 5-mg/mL solution of melphalan.<sup>3172</sup> The appropriate dose of the reconstituted solution should be withdrawn from the vial and diluted with sodium chloride 0.9% to a concentration of 0.45 mg/mL.<sup>3172</sup>

### Equivalency

Melphalan hydrochloride 56 mg is equivalent to 50 mg of melphalan free base.<sup>3172</sup>

### Trade Name(s)

Alkeran, Evomela

### Administration

Melphalan hydrochloride is administered intravenously as an infusion.<sup>3172 3173 3425 3426</sup> The manufacturers recommend that the drug be administered slowly into a fast-running intravenous infusion solution via a central venous line or injection port.<sup>3172 3173</sup>

The final diluted solution of melphalan (generic versions of Alkeran) for infusion is administered over at least 15 minutes (usually 15 to 20 minutes).<sup>3173 3425 3426</sup>

The final diluted solution of melphalan (Evomela) for infusion is administered over 15 to 20 minutes or 30 minutes, depending on the indication.<sup>3172</sup>

Extravasation of melphalan hydrochloride may cause local tissue damage and should be avoided.<sup>3172 3173 3425 3426</sup> The drug should *not* be administered by direct injection into a peripheral

vein.<sup>3172 3173 3425 3426</sup> In cases of poor peripheral access, consideration should be given to the use of a central venous line.<sup>3173 3425 3426</sup>

As with other toxic drugs, caution should be exercised in the handling and preparation of melphalan hydrochloride and applicable special handling and disposal procedures should be followed.<sup>3172 3173 3425 3426</sup> Some manufacturers recommend the use of gloves as skin reactions may occur with accidental exposure.<sup>3173 3425 3426</sup> If skin or mucosal contact with the drug occurs, the affected area(s) should be washed immediately and thoroughly with soap and water.<sup>3173 3425 3426</sup>

### Stability

Intact vials should be stored at controlled room temperature and protected from light;<sup>3172 3173 3425 3426</sup> some manufacturers recommend storage in the original carton.<sup>3173 3425</sup>

The solution should be visually inspected for particulate matter and discoloration prior to administration; if particulate matter is present or discoloration occurs, the solution should not be used.<sup>3172 3173 3425 3426</sup>

The reconstituted solution of melphalan (generic versions of Alkeran) should *not* be refrigerated; a precipitate forms in the reconstituted product if stored at 5°C.<sup>3173 3425 3426</sup>

### Melphalan Hydrochloride (generic versions of Alkeran)

The time between reconstitution and dilution and administration of solutions of melphalan (generic versions of Alkeran) should be minimized.<sup>3173 3425 3426</sup> In as little as 30 minutes from reconstitution, a citrate derivative of melphalan has been detected; upon further dilution with sodium chloride 0.9%, nearly 1% of the drug is hydrolyzed every 10 minutes.<sup>3173 3425 3426</sup> Manufacturers recommend that administration of melphalan hydrochloride be completed within 60 minutes of reconstitution.<sup>3173 3425 3426</sup>

### Melphalan Hydrochloride (Evomela, Spectrum)

The manufacturer states that the 5-mg/mL reconstituted solution of Evomela is stable for 1 hour at room temperature or 24 hours under refrigeration at 5°C without any precipitation because of its high solubility.<sup>3172</sup> After dilution of Evomela to a melphalan concentration of 0.45 mg/mL in sodium chloride 0.9%, this formulation is stable for 4 hours at room temperature in addition to the 1 hour at room temperature following reconstitution.<sup>3172</sup>

One study found that a 5-mg/mL reconstituted solution of melphalan (as the Evomela formulation) was stable for 25 hours at room temperature based on experimental trend analysis and for up to 48 hours when stored at 2 to 8°C.<sup>3171 3427</sup> At 2 to 8°C, the 5-mg/mL reconstituted solution exhibited an antimicrobial effect for up to 72 hours against 8 microorganisms tested in the study (*Aspergillus brasiliensis*, *Candida albicans*, *Bacillus subtilis*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Staphylococcus*

*aureus*, methicillin-resistant *S. aureus* [MRSA], and vancomycin-resistant *Enterococcus faecalis* [VRE]).<sup>3171</sup> Concentrations of 0.45, 1, and 2 mg/mL diluted in sodium chloride 0.9% were calculated to be stable for a time of 4, 7, and 11 hours, respectively, based on experimental trend analysis.<sup>3171 3427</sup>

### pH Effects

Melphalan is most stable over a pH range of 3 to 7; decomposition increases at pH 9.<sup>971</sup>

### Sorption

Melphalan (GlaxoWellcome) 60 mcg/mL in sodium chloride 0.9% exhibited no loss due to sorption in polyethylene, polyvinyl chloride (PVC) containers, and glass containers over 24 hours under refrigeration and 8 hours at room temperature.<sup>2420 2430</sup>

### Filtration

Melphalan 20 mcg/mL in 1 mL of sodium chloride 0.9% was filtered through the following filters; minimal adsorption occurred in all cases.<sup>970</sup>

Filter	Delivered Concentration (% of initial)
Cellulose acetate 0.2 µm (Minisart-N, Sartorius)	99
Polysulfone 0.45 µm (Acrodisc, Gelman)	98
Polytetrafluoroethylene 0.45 µm (Acrodisc-CR, Gelman)	96

Sodium chloride 0.9%	<sup>b</sup>	GSK	2 g	Physically compatible. Less than 10% loss in 24 hr at 5°C protected from light	3174	C
Sodium chloride 0.9%	<sup>b</sup>	GSK	4 g	Turbidity and discoloration in 4 hr at 5°C protected from light	3174	I
Sodium chloride 0.9%	<sup>b</sup>	GSK	4 g	Physically compatible. Less than 10% loss in 8 hr at 25°C	3174	C
Sodium chloride 0.9%		SP <sup>c</sup>	450 mg	Stated to be stable for 4 hr at room temperature	3172	C

<sup>a</sup> Incompatible by conventional standards. May be used in shorter time periods.

<sup>b</sup> Tested in PVC containers.

<sup>c</sup> Test performed using the Evomela formulation.

## Meperidine Hydrochloride

AHFS 28:08.08

### Pethidine Hydrochloride

#### Products

Meperidine hydrochloride is available in concentrations of 10, 25, 50, 75, and 100 mg/mL in a variety of packaging sizes and configurations, including ampuls, vials, and disposable cartridge units.<sup>1(10/06)</sup> Some products also contain an antioxidant such as sodium metabisulfite and antibacterial preservatives such as phenol and metacresol.<sup>4</sup>

#### pH

The pH is adjusted to 3.5 to 6.<sup>1(10/06)</sup> <sup>4</sup>

#### Osmolality

The osmolality of meperidine hydrochloride 50 mg/mL was determined to be 302 mOsm/kg.<sup>1233</sup>

#### Trade Name(s)

Demerol

#### Administration

Meperidine hydrochloride is administered by intramuscular injection into a large muscle mass. It may also be given subcutaneously or slowly by intravenous injection or infusion in a diluted solution.<sup>1(10/06)</sup> <sup>4</sup> A 10-mg/mL concentration has been recommended for slow intravenous injection. The 10-mg/mL commercial injection does not require further dilution and is for use with a compatible infusion device. Intravenous infusion of a 1-mg/mL concentration has been used to supplement anesthesia.<sup>4</sup>

#### Stability

Meperidine hydrochloride should be stored at controlled room temperature and protected from light and freezing.<sup>4</sup>

#### Syringes

Meperidine hydrochloride (Wyeth) 5 and 10 mg/mL in dextrose 5% and sodium chloride 0.9% was packaged in 30-mL Plastipak (Becton Dickinson) syringes capped with Monoject (Sherwood) tip caps. Syringes were stored at 23°C exposed to light and protected from light, 4°C protected from light, and frozen at -20°C protected from light for 12 weeks. Both concentrations at all storage conditions were stable for at least 12 weeks.<sup>1894</sup>

Preservative-free meperidine hydrochloride (Abbott) was diluted to concentrations of 0.25, 1, 10, 20, and 30 mg/mL with dextrose 5% and with sodium chloride 0.9%. The solutions were packaged in 60-mL polypropylene syringes (Becton Dickinson), sealed with Luer lock caps, and stored at 22 and 4°C for 28 days protected from light. The solutions were visually colorless and free of precipitation over the course of the study. Little or no loss of meperidine hydrochloride occurred in either solution at either temperature in 28 days.<sup>2200</sup>

#### Sorption

Meperidine hydrochloride was shown not to exhibit sorption to PVC bags and tubing, polyethylene tubing, Silastic tubing, and polypropylene syringes.<sup>536 606</sup>

#### Central Venous Catheter

Meperidine hydrochloride (Wyeth) 4 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Tested in Ringer's injection, lactated.

<sup>d</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>e</sup> Tested in bacteriostatic sodium chloride 0.9% preserved with benzyl alcohol 0.9%.

<sup>f</sup> Nesiritide is incompatible with bisulfite antioxidants used in some drug formulations. The specific formulation of the product to be used should be checked to ensure that no sulfite antioxidants are present.

<sup>g</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>h</sup> Tested in dextrose 5% in Ringer's injection, lactated.

<sup>i</sup> Tested in sodium chloride 0.45%.

<sup>j</sup> Lyophilized formulation tested.

<sup>k</sup> Ampicillin component. Ampicillin in a 2:1 fixed-ratio concentration with sulbactam.

<sup>l</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>m</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>n</sup> Not specified whether concentration refers to single component or combined components.

<sup>o</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>p</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>q</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>r</sup> Test performed using the formulation WITH edetate disodium.

## Additional Compatibility Information

### *Chlorpromazine and Hydroxyzine*

Chlorpromazine hydrochloride (Elkins-Sinn) 6.25 mg/mL, hydroxyzine hydrochloride (Pfizer) 12.5 mg/mL, and meperidine hydrochloride (Winthrop) 25 mg/mL, in both glass and plastic syringes, have been reported to be physically compatible and chemically stable for at least 1 year at 4 and 25°C when protected from light.<sup>989</sup>

### *Chlorpromazine and Promethazine*

Chlorpromazine hydrochloride, meperidine hydrochloride, and promethazine hydrochloride combined as an extemporaneous mixture for preoperative sedation, developed a brownish-yellow color after 2 weeks of storage with protection from light. The discoloration was attributed to the metacresol preservative content of the meperidine hydrochloride product used. Use of meperidine hydrochloride which contains a different preservative resulted in a solution that remained clear and colorless for at least 3 months when protected from light.<sup>1148</sup>

Selected Revisions January 31, 2020. © Copyright, October 1982. American Society of Health-System Pharmacists, Inc.

## Mepivacaine Hydrochloride

AHFS 72:00

### Products

Mepivacaine hydrochloride is available in concentrations of 1, 1.5, and 2%. Methylparaben is incorporated into multiple-dose containers, but single-dose containers may be preservative free. The pH may have been adjusted with sodium hydroxide and/or hydrochloric acid.<sup>1(5/06) 4</sup>

### pH

From 4.5 to 6.8.<sup>1(5/06) 4</sup>

### Osmolality

Mepivacaine hydrochloride injections are isotonic.<sup>1(5/06)</sup>

### Trade Name(s)

Carbocaine, Polocaine, Polocaine-MPF

### Administration

Mepivacaine hydrochloride may be administered by infiltration and by peripheral or sympathetic nerve block. Mepivacaine

hydrochloride *without* preservatives may be administered by epidural block, including caudal anesthesia; forms containing preservatives should not be administered by this route<sup>4</sup>.

### Stability

Mepivacaine hydrochloride in intact containers should be stored at controlled room temperature and protected from temperatures above 40°C and from freezing. Mepivacaine hydrochloride is resistant to hydrolysis and may be autoclaved repeatedly.<sup>1(5/06) 4</sup> However, mepivacaine hydrochloride in dental cartridges should not be subjected to autoclaving because of breakdown of the dental cartridge closures.<sup>4</sup>

### Syringes

The stability of mepivacaine (salt form unspecified) 10 mg/mL repackaged in polypropylene syringes was evaluated. Little change in concentration was found after four weeks of storage at room temperature not exposed to direct light.<sup>2164</sup>

# Meropenem

**AHFS 8:12.07.08**

## Products

Meropenem is available as a dry powder in single-use 20- and 30-mL vials containing 500 mg and 1 g, respectively, of meropenem (as the trihydrate).<sup>3102</sup> Vials also contain anhydrous sodium carbonate.<sup>3102</sup>

For intravenous bolus injection administration, the 500-mg and 1-g vials should be reconstituted with 10 and 20 mL, respectively, of sterile water for injection.<sup>3102</sup> Vials should be shaken to dissolve the vial contents and allowed to stand until the solution is clear.<sup>3102</sup> Each mL of the resultant solution contains approximately 50 mg of meropenem.<sup>3102</sup>

For intravenous infusion administration, vials may be reconstituted directly with a compatible infusion solution.<sup>3102</sup> Alternatively, the appropriate dose of the reconstituted meropenem solution may be transferred to an intravenous container and further diluted with an appropriate infusion solution (e.g., sodium chloride 0.9%, dextrose 5%).<sup>3102</sup>

For intravenous infusion, meropenem also is available in dual-chamber single-use flexible containers containing 500 mg or 1 g of meropenem (as the trihydrate) with sodium carbonate.<sup>3103</sup> The diluent chamber contains 50 mL of sodium chloride 0.9%.<sup>3103</sup> If meropenem doses less than the full dose supplied in the container are needed, the manufacturer states that these containers should not be used.<sup>3103</sup> Specific product labeling should be consulted for instructions on reconstitution (activation) of the dual-chamber container.<sup>3103</sup>

## pH

The freshly reconstituted solution has a pH ranging from 7.3 to 8.3.<sup>3102 3103</sup>

## Osmolality

Meropenem 500 mg or 1 g in dual-chamber single-use flexible containers has an osmolality of approximately 356 or 417 mOsm/kg, respectively, when activated with the sodium chloride 0.9% diluent.<sup>3103</sup>

## Sodium Content

Each gram of meropenem in single-use vials provides 3.92 mEq (90.2 mg) of sodium from the sodium carbonate present in the formulation.<sup>3102</sup>

After reconstitution with the sodium chloride 0.9% diluent, each dual-chamber container of meropenem 500 mg or 1 g provides 10.7 mEq (245.1 mg) or 12.6 mEq (290.2 mg), respectively, of sodium.<sup>3103</sup>

## Trade Name(s)

Merrem I.V.

## Administration

Meropenem is administered by intravenous bolus injection of 5 to 20 mL over 3 to 5 minutes<sup>3102</sup> or by intravenous infusion

diluted in a compatible infusion solution over 15 to 30 minutes.<sup>3102 3103</sup>

Extended infusion strategies for meropenem have been examined in the literature;<sup>2261 2568 3104 3105 3106</sup> however, the poor stability of the drug, particularly at room temperature, typically limits the use of such strategies.<sup>2261 3105</sup>

## Stability

Intact vials of meropenem should be stored at a controlled room temperature of 20 to 25°C.<sup>3102</sup> The drug is a white to pale yellow powder that yields a colorless to yellow solution depending on the concentration.<sup>3102</sup>

For intravenous bolus administration, the manufacturer indicates that solutions of meropenem reconstituted in vials with sterile water for injection at concentrations of up to 50 mg/mL are stable for up to 3 hours at temperatures of up to 25°C and for 13 hours at temperatures of up to 5°C.<sup>3102</sup>

For administration by intravenous infusion, meropenem solutions in sodium chloride 0.9% at a concentration of 1 to 20 mg/mL are stated to be stable for 1 hour at temperatures of up to 25°C or 15 hours at temperatures of up to 5°C.<sup>3102</sup> Intravenous infusion solutions prepared in dextrose 5% at these concentrations should be used immediately.<sup>3102</sup>

Unactivated, dual-chamber meropenem containers should be stored at a controlled room temperature of 20 to 25°C.<sup>3103</sup> Once the foil strip has been removed from the drug chamber, the product must be protected from light and used within 7 days or the labeled expiration date, whichever occurs first.<sup>3103</sup> Once reconstituted (activated), the drug should be used within 1 hour if stored at room temperatures of up to 25°C or 15 hours if stored under refrigeration at temperatures of up to 5°C.<sup>3103</sup>

Meropenem 50 mg/mL reconstituted with sodium chloride 0.9% is reported to reach 10% loss in 4.8 hours at 25°C.<sup>2697</sup>

Meropenem (AstraZeneca) 1 g reconstituted with 20 mL of water for injection and diluted with 50 mL of sodium chloride 0.9% was stored in polyvinyl chloride (PVC) infusion bags.<sup>3517</sup> Yellow discoloration was observed after 7 hours in solutions stored at 33°C and after 12 hours in solutions stored at 22°C.<sup>3517</sup>

## Concentration Effects

Degradation of meropenem is concentration dependent.<sup>3104 3106 3298</sup> Meropenem has demonstrated improved stability in solution at concentrations of 40 g/L or lower.<sup>3104 3106</sup>

In one study, reconstituting meropenem with sterile water for injection to concentrations exceeding 64 g/L resulted in unacceptably viscous solutions that impeded flow from elastomeric pumps to less than 75% of the nominal flow rate.<sup>3105</sup>

## Temperature Effects

Degradation of meropenem also is temperature dependent.<sup>3104 3105 3106</sup> Meropenem has demonstrated improved stability in

solution at temperatures less than or equal to 25°C.<sup>3104 3105 3106</sup> Meropenem (AstraZeneca) 5 mg/mL in sodium chloride 0.9% exceeded 10% drug loss by 12, 8, and 6 hours at temperatures of 30, 35, and 40°C, respectively.<sup>3109</sup>

### Freezing Solutions

Manufacturers state that solutions of meropenem should not be frozen.<sup>3102 3103</sup>

### Syringes

Meropenem (AstraZeneca; Fresenius Kabi; Hospira; Sandoz) was diluted to concentrations of 10, 20, and 40 mg/mL in sodium chloride 0.9% and stored in polypropylene syringes (Becton

Dickinson).<sup>3298</sup> Solutions containing meropenem 10 and 20 mg/mL were stable for 12 hours at 25°C; solutions containing meropenem 40 mg/mL were stable for 8 hours at 25°C.<sup>3298</sup>

### Central Venous Catheter

Meropenem (Zeneca) 5 mg/mL in sodium chloride 0.9% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Meropenem–Vaborbactam

AHFS 8:12.07.08

### Products

The fixed combination of meropenem–vaborbactam is available as a powder in single-dose (preservative-free) vials containing 2 g (meropenem 1 g [as the trihydrate] plus vaborbactam 1 g) and sodium carbonate 0.575 g.<sup>3379</sup>

The contents of each 2-g vial should be reconstituted with 20 mL of sodium chloride 0.9% (withdrawn from an infusion bag) and mixed gently to dissolve the powder.<sup>3379</sup> The reconstituted solution will have approximate meropenem and vaborbactam concentrations of 50 mg/mL each.<sup>3379</sup> The reconstituted solution is *not* suitable for direct injection.<sup>3379</sup>

The reconstituted solution must be diluted immediately in the infusion bag containing sodium chloride 0.9% from which the volume used for reconstitution of the appropriate dose was withdrawn.<sup>3379</sup> The manufacturer's instructions for preparing various doses of meropenem–vaborbactam from the reconstituted solution are as follows:<sup>3379</sup>

For 4 g (meropenem 2 g plus vaborbactam 2 g), withdraw the entire contents (i.e., approximately 21 mL each) of 2 vials and add to an infusion bag containing 250, 500, or 1000 mL of sodium chloride 0.9% (less the 40 mL used for reconstitution).

For 2 g (meropenem 1 g plus vaborbactam 1 g), withdraw the entire contents (i.e., approximately 21 mL) of 1 vial and add to an infusion bag containing 125, 250, or 500 mL of sodium chloride 0.9% (less the 20 mL used for reconstitution).

For 1 g (meropenem 0.5 g plus vaborbactam 0.5 g), withdraw 10.5 mL and add to an infusion bag containing 70, 125, or 250 mL of sodium chloride 0.9% (less the 20 mL used for reconstitution).

### Sodium Content

Each 2-g vial of this fixed combination contains 0.25 g (10.9 mEq) of sodium.<sup>3379</sup>

### Trade Name(s)

Vabomere

### Administration

The diluted solution of meropenem–vaborbactam for infusion is administered intravenously over 3 hours.<sup>3379</sup> The reconstituted solution is *not* suitable for direct injection.<sup>3379</sup>

### Stability

Meropenem–vaborbactam is a white to light yellow powder that forms a colorless to light yellow solution upon both reconstitution and dilution.<sup>3379</sup> Intact vials of meropenem–vaborbactam should be stored at controlled room temperature.<sup>3379</sup>

Diluted solutions of meropenem–vaborbactam for infusion should be visually inspected for particulate matter and discoloration prior to administration.<sup>3379</sup> Administration of the diluted solution for infusion must be completed within 4 hours if stored at room temperature or 22 hours if stored at 2 to 8°C.<sup>3379</sup> Any unused portions should be discarded.<sup>3379</sup>

Meropenem–vaborbactam reconstituted and diluted for infusion demonstrated less than 10% loss of either drug when stored for up to 10 hours at room temperature and for up to 26 hours under refrigeration (5°C); however, a degradation product formation assessment revealed that the solution did not consistently meet impurity limits during this period.<sup>3381</sup>

# Mesna

## AHFS 92:56

### Products

Mesna is available as a 100-mg/mL solution in 10-mL multi-dose vials. Each mL of solution also contains edetate disodium 0.25 mg and sodium hydroxide to adjust the pH. In addition, the multidose vials contain benzyl alcohol 10.4 mg/mL.<sup>1(5/06)</sup>

### pH

The pH of mesna injection is stated to be pH 6.5 to 7.3 or pH 7.5 to 8.5, depending on the specific product.<sup>1(5/06)</sup>

### Trade Name(s)

Mesnex

### Administration

Mesna may be administered by intravenous injection or infusion.<sup>1(5/06)</sup> 4 Infusion is usually performed over 15 to 30 minutes, but continuous infusion has also been utilized.<sup>4</sup> Dilution to a concentration of 20 mg/mL in a compatible solution is recommended for intravenous infusion.<sup>1(5/06)</sup> 4

### Stability

Intact ampuls of mesna should be stored at controlled room temperature. The solution is clear and colorless<sup>1(5/06)</sup> and is not light sensitive.<sup>72</sup> When exposed to oxygen, mesna oxidizes to the disulfide form, dimesna. Unused mesna injection in opened ampuls should be discarded after dose preparation. However, the multidose vials may be stored and used for up to 8 days after initial entry.<sup>1(5/06)</sup> 4

### pH Effects

Mesna and ifosfamide have been found to be stable in combined admixtures.<sup>72 1380 1494 1495 1496</sup> However, mesna has been found to undergo more extensive decomposition when mixed with ifosfamide in an infusion solution made alkaline with sodium bicarbonate. At pH 8, mesna was stable for 6 hours, but lost about 13% in 24 hours and 23% in 48 hours. Ifosfamide underwent only 6% loss in 24 hours, but lost 14% in 48 hours.<sup>2281</sup>

### Syringes

The short-term use of plastic syringes for preparing mesna infusions appears to be satisfactory. However, extended storage of mesna in a plastic and a glass syringe resulted in the formation of dark or thread-like particles and a change in viscosity after 12 hours at room temperature.<sup>72</sup>

Mesna (Asta Pharma) 100 mg/mL was packaged as 10 mL in 20-mL polypropylene syringes (Becton Dickinson). Samples having the air expelled from the syringes were stored at 5, 24, and 35°C, and samples with air drawn into the syringes were stored at 24°C. After 9 days of storage, little or no change in the mesna concentration was found in all samples with no air present. The maximum loss was less than 4% found in the samples stored at 35°C. However, the syringes containing air exhibited 10% loss in 8 days at 24°C. Minimizing the exposure of mesna to air during storage was recommended to slow the formation of dimesna.<sup>2181</sup>

## Methadone Hydrochloride

AHFS 28:08.08

### Products

Methadone hydrochloride is available in 20-mL multidose vials. Each mL of solution contains methadone hydrochloride 10 mg and sodium chloride 0.9% with sodium hydroxide and/or hydrochloric acid to adjust the pH. In addition, the 20-mL vials contain chlorobutanol 0.5%.<sup>1(3/06)</sup>

### pH

From 4.5 to 6.5.<sup>1(3/06)</sup>

### Administration

Methadone hydrochloride may be administered by subcutaneous, intramuscular, or intravenous injection.<sup>1(3/06)</sup> 4

### Stability

Methadone hydrochloride in intact vials should be stored at controlled room temperature and protected from light.<sup>1(3/06)</sup>

### Syringes

In 2015, reports of decreased potency of certain drugs (e.g., methadone hydrochloride) stored in Becton Dickinson syringes for extended periods (i.e., exceeding 24 hours) were confirmed by the manufacturer of these syringes; the cause of this change was later identified to be the inclusion of an alternate rubber stopper in the plunger of certain product lots of syringes.<sup>3029 3036 3037 3039 3041 3042</sup> Decreased potency was not observed when the syringes were filled and used promptly.<sup>3037</sup> Use of the alternate stopper was later discontinued and use of the primary stopper in such syringes was resumed; however, Becton Dickinson states that its general-use syringes are cleared by FDA for immediate use in fluid aspiration and injection and that such syringes, regardless of the stopper material, have not been cleared by FDA for use as a closed-container system.<sup>3391</sup>

## Methocarbamol

AHFS 12:20.04

### Products

Methocarbamol 100 mg/mL is available in 10-mL vials. Also present in the formulation is polyethylene glycol 300 50% in water for injection with sodium hydroxide and/or hydrochloric acid to adjust pH during manufacturing.<sup>1(8/06)</sup>

### pH

From 3.5 to 6.0.<sup>1(8/06)</sup>

### Tonicity

Methocarbamol injection is hypertonic.<sup>4</sup>

### Trade Name(s)

Robaxin

### Administration

Methocarbamol injection is administered intramuscularly or intravenously. It should not be given subcutaneously. For

intramuscular injection, not more than 5 mL (500 mg) should be given into each gluteal region. Direct intravenous injection should be made slowly at a maximum rate of 3 mL (300 mg) per minute. For intravenous infusion, 1 g of methocarbamol may be diluted in 250 mL of dextrose 5% or sodium chloride 0.9%.<sup>1(8/06)</sup>

### Stability

Store at controlled room temperature<sup>1(8/06)</sup> and protect from freezing. Methocarbamol was stable for up to six days when diluted in sterile water for injection, dextrose 5%, or sodium chloride 0.9% to a concentration of 4 mg/mL. Refrigeration of methocarbamol diluted for intravenous infusion to concentrations of 15.4 mg/mL and greater may result in precipitation.<sup>4</sup>

## Methohexital Sodium

AHFS 28:04.04

### Products

Methohexital sodium is available in single-use vials containing methohexital sodium 200 mg with anhydrous sodium carbonate 12 mg and multiple-use vials containing methohexital sodium 500 mg with anhydrous sodium carbonate 30 mg or methohexital sodium 2.5 g with anhydrous sodium carbonate 150 mg.<sup>2926</sup> Recommended diluents are based on the intended route of administration.<sup>2926</sup> Diluents containing bacteriostatic agents should *not* be used.<sup>2926</sup>

To prepare a 1% (10-mg/mL) solution of methohexital sodium for intermittent intravenous injection, reconstitute the 200-mg single-use or the 500-mg multiple-use vials with 20 or 50 mL, respectively, of diluent.<sup>2926</sup> For the 2.5-g multiple-use vial, reconstitute with 15 mL of diluent and further dilute by adding the drug to 235 mL of diluent to total 250 mL.<sup>2926</sup> The preferred diluent for intermittent intravenous injection is sterile water for injection, but dextrose 5% or sodium chloride 0.9% also may be used.<sup>2926</sup>

Initial dilution of the 2.5-g vial results in a yellow solution.<sup>2926</sup> When further diluted to a final concentration of 1%, the solution must be clear and colorless or it should not be used.<sup>2926</sup>

To prepare a 0.2% (2-mg/mL) solution of methohexital sodium for continuous intravenous infusion, reconstitute the 500-mg vial with 15 mL of diluent and further dilute by adding the drug to 235 mL of diluent to total 250 mL.<sup>2926</sup> For continuous intravenous infusion, use only dextrose 5% or sodium chloride 0.9% as a diluent.<sup>2926</sup> Do *not* use sterile water for injection to prepare this concentration for continuous intravenous infusion to avoid extreme hypotonicity.<sup>2926</sup>

To prepare a 5% (50-mg/mL) solution for intramuscular use, reconstitute the 200- or 500-mg vials with 4 or 10 mL, respectively, of diluent.<sup>2926</sup> For the 2.5-g vial, reconstitute with 50 mL of diluent.<sup>2926</sup> No further dilution of the reconstituted solution for intramuscular use is required.<sup>2926</sup> The preferred diluent for intramuscular use is sterile water for injection, but sodium chloride 0.9% also may be used.<sup>2926</sup>

### pH

A 0.2% solution in dextrose 5% has a pH of 9.5 to 10.5; a 1% solution in sterile water for injection has a pH of 10 to 11.<sup>2926</sup>

### Sodium Content

Methohexital sodium contains 4.652 mEq of sodium per gram of drug; the sodium carbonate provides 1.132 mEq while the balance comes from the drug itself.<sup>869</sup>

### Trade Name(s)

Brevital Sodium

### Administration

Methohexital sodium is administered intravenously, by intermittent injection at a concentration of 1% or by continuous infusion at a concentration of 0.2%.<sup>2926</sup> Intra-arterial injection and extravasation should be avoided.<sup>2926</sup>

Intramuscular injection of 5% solutions of methohexital sodium has also been described.<sup>2926</sup>

### Stability

Intact vials should be stored at controlled room temperature.<sup>2926</sup> Reconstituted solutions of methohexital sodium are stable at room temperature for 24 hours.<sup>2926</sup>

The manufacturer states that Ringer's injection, lactated is incompatible as a diluent; the potential for incompatibility exists between the sodium carbonate in the drug formulation and the calcium ions of the infusion solution.<sup>282 2926</sup>

### pH Effects

Methohexital sodium is alkaline in solution and is incompatible with acidic solutions and phenol-containing solutions.<sup>4</sup>

Methohexital sodium exhibits poor solubility in an acidic medium and may precipitate in solutions containing acidic drugs.<sup>22</sup>

Since solubility is maintained only at relatively high pH, mixing methohexital sodium with acidic solutions is not recommended.<sup>4</sup> Mixed with methohexital sodium, a haze or precipitate forms in 15 minutes with atropine sulfate, in 30 minutes with succinylcholine chloride, and in 60 minutes with scopolamine HBr.<sup>2926</sup>

When barbiturates are mixed with succinylcholine chloride, either free barbiturate precipitates or the succinylcholine chloride is hydrolyzed, depending on the final pH of the admixture.<sup>4 21</sup> Similarly, atracurium besylate may be inactivated by alkaline solutions, such as barbiturates, and a free acid of the admixed drug may precipitate, depending on the resultant pH of the admixture.<sup>4</sup>

Methohexital sodium may raise the pH of admixture solutions to the alkaline range and, therefore, should not be mixed with drugs that are alkali labile.<sup>4</sup>

### Sorption

Methohexital sodium (Lilly) 32 mg/L displayed 7.9% sorption to a PVC plastic test strip in 24 hours.<sup>12</sup> However, another test did not confirm this finding. No significant loss in PVC containers and no difference between glass and PVC containers were found.<sup>282</sup>

# Methotrexate Sodium

## AHFS 10:00

### Products

Methotrexate sodium is available in liquid<sup>2966 2967</sup> and lyophilized dosage forms.<sup>2968</sup>

The liquid dosage forms contain methotrexate sodium equivalent to methotrexate 25 mg/mL and are available in vials of various sizes from 2 to 40 mL.<sup>2966 2967</sup> The products also contain sodium chloride,<sup>2966 2967</sup> and the preserved products contain benzyl alcohol.<sup>2966</sup> The pH has been adjusted during manufacturing with sodium hydroxide and/or hydrochloric acid.<sup>2966 2967</sup>

Methotrexate (as the sodium salt) is available as a lyophilized powder in single-use vials containing 1 g.<sup>2968</sup> The pH may have been adjusted during manufacturing with sodium hydroxide and/or hydrochloric acid.<sup>2968</sup> The 1-g vial requires 19.4 mL of sterile, preservative-free diluent (e.g., dextrose 5%, sodium chloride 0.9%) for reconstitution to yield a 50-mg/mL concentration.<sup>2968</sup>

Methotrexate also is available in prefilled auto-injector syringes for subcutaneous use containing 50 mg/mL in various sizes from 0.15 to 0.6 mL.<sup>2970</sup> Prefilled auto-injector syringes for subcutaneous use also are available containing 7.5, 10, 15, 20 or 25 mg per 0.4 mL.<sup>2969</sup>

### pH

The pH of the liquid forms in vials is approximately 8.5.<sup>2966 2967</sup> The pH of the lyophilized form is approximately 8.5 to 8.7.<sup>2968</sup> The pH of the Otrexup and Rasuvo prefilled auto-injector syringes is 8 and 8.5, respectively.<sup>2969 2970</sup>

### Tonicity

The liquid forms of methotrexate sodium in vials are isotonic.<sup>2966 2967</sup>

### Sodium Content

Methotrexate sodium preservative-free liquid injections in vials contain sodium 0.43, 0.86, 1.72, 2.15, and 8.6 mEq in the 2-, 4-, 8-, 10-, and 40-mL sizes, respectively.<sup>2967</sup> The lyophilized product contains 7 mEq of sodium in the 1-g vial.<sup>2968</sup>

### Trade Name(s)

Otrexup, Rasuvo

### Administration

Methotrexate sodium may be administered by intramuscular, intra-arterial, subcutaneous, or intrathecal injection, by direct intravenous injection, or by intravenous infusion.<sup>2966 2967 2968 2969 2970</sup> For intrathecal injection, a preservative-free form is diluted to a 1-mg/mL concentration in an appropriate preservative-free diluent (e.g., sodium chloride 0.9%, Elliott's B solution, the patient's own spinal fluid).<sup>4 435 830 2967 2968</sup>

For high-dose regimens, it is recommended that preservative-free forms of methotrexate sodium be used.<sup>241 242 2967 2968</sup>

The manufacturer of the lyophilized powder form of methotrexate sodium states that high doses of methotrexate administered by intravenous infusion are to be diluted in dextrose 5%.<sup>2968</sup> High doses of methotrexate sodium require leucovorin rescue.<sup>2967 2968</sup>

### Stability

Store the lyophilized powder and injection vials and the prefilled auto-injector syringes at controlled room temperature with protection from light.<sup>2966 2967 2968 2969 2970</sup> Retain the lyophilized form in its original carton until use.<sup>2968</sup>

For intrathecal injection, the preservative-free dosage forms should be diluted immediately prior to use.<sup>2967</sup> Although reconstitution of the lyophilized vials immediately prior to use is also recommended (because of the absence of antibacterial preservatives),<sup>2968</sup> the reconstituted solution is stable for at least 1 week at room temperature.<sup>234</sup>

Immersion of a needle with an aluminum component in methotrexate sodium (Lederle) 25 mg/mL resulted in the formation of orange crystals on the aluminum surface after 36 hours at 24°C with protection from light.<sup>988</sup>

### pH Effects

Methotrexate is most stable between pH 6 and 8. Drugs producing extremes of pH should not be added to methotrexate.<sup>1072 1379</sup>

### Freezing Solutions

Methotrexate sodium (Lederle) 50 mg/100 mL in polyvinyl chloride (PVC) bags of dextrose 5% (Travenol) was frozen at -20°C for at least 30 days and thawed by microwave radiation for 2 minutes with no significant change in concentration. Even after 5 repetitions of the freeze-thaw treatment, the methotrexate concentration showed no significant change.<sup>818</sup>

The stability of methotrexate 5 mg, 50 mg, and 1 g in 50 mL of sodium chloride 0.9% in PVC bags frozen at -20°C for up to 12 weeks and thawed in a microwave oven was evaluated. No loss was found in any of the concentrations.<sup>1281</sup>

### Light Effects

Photolability, although unrecognized for many years, is a stability problem that is increased by dilution and mixture with sodium bicarbonate.<sup>1202</sup>

In dilute solutions of 0.1 mg/mL, methotrexate is reported to undergo photodegradation on exposure to light. Decomposition of 5 to 8% in 10 days and 11 to 17% in 20 days has been reported. This effect was not observed in the more concentrated solutions of the commercial preparation (25 mg/mL)<sup>433</sup> or in admixtures of methotrexate during short-term light exposure. No significant loss of methotrexate occurred due to light exposure for 4 hours in solutions composed of 5 mg, 50 mg, or 1 g of methotrexate in 50 mL of sodium chloride 0.9% in PVC containers.<sup>1281</sup>

Little methotrexate loss was found from a 1-mg/mL solution in sodium chloride 0.9% in 3 burette drip chambers made of cellulose propionate (Avon A200 standard and A2000 Amberset) and methacrylate butadiene styrene (Avon A2001 Sureset) when exposed to normal mixed daylight and fluorescent lighting conditions for 24 hours. However, in 48 hours about 10 and 12% losses were observed in the A200 and A2001, respectively. With exposure to direct sunlight, an 11% loss occurred in the A200 in 7 hours. No loss occurred when the Amberset or Sureset was wrapped in foil and exposed to either light condition for 48 hours.<sup>1378</sup>

Exposure of methotrexate 1-mg/mL solution in PVC and polybutadiene tubing to mixed daylight and fluorescent light produced significant losses after 8 to 12 hours. The Amberset PVC tubing or foil wrapping for the polybutadiene tubing to protect solutions from light reduced losses to 12 to 16% in 48 hours.<sup>1378</sup>

Methotrexate sodium (R. Bellon), reconstituted to a concentration of 1 mg/mL with sodium chloride 0.9%, was evaluated for stability in translucent containers (Perfupack, Baxter) and 5 opaque containers (green PVC Opafuseur [Bruneau], white EVA Perfu-opaque [Baxter], orange PVC PF170 [Cair], white PVC V86 [Codan], and white EVA Perfecran [Fandre]) when exposed to sunlight for 28 days. Photodegradation was found after storage in the translucent Perfupack. Losses ranged from 18.5 to 27% after 24 hours at a methotrexate sodium concentration of 5 mg/mL. At 1 mg/mL, losses of 4% or less occurred in 24 hours in the opaque containers.<sup>1750</sup>

### **Intrathecal Injections**

In a study of intrathecal injections, preservative-free methotrexate sodium (Ben Venue) was reconstituted to a concentration of 2.5 mg/mL with Elliott's B solution (305 mOsm/kg, pH 7.2), sodium chloride 0.9% injection (303 mOsm/kg, pH 7.6), or Ringer's injection, lactated (270 mOsm/kg, pH 7.6). In all 3 solutions, methotrexate exhibited no change in concentration over 7 days under fluorescent light at 30°C.<sup>327</sup>

In another study, the stability and compatibility of cytarabine (Upjohn), methotrexate (NCI), and hydrocortisone (Upjohn), mixed together in intrathecal injections, were evaluated. Two combinations were tested: (1) cytarabine 50 mg, methotrexate 12 mg (as the sodium salt), and hydrocortisone 25 mg (as the sodium succinate salt); and (2) cytarabine 30 mg, methotrexate 12 mg (as the sodium salt), and hydrocortisone 15 mg (as the sodium succinate salt). Each drug combination was added to 12 mL of Elliott's B solution (NCI), sodium chloride 0.9% (Abbott), dextrose 5% (Abbott), and Ringer's injection, lactated (Abbott) and stored for 24 hours at 25°C. Cytarabine and methotrexate were both chemically stable, with no drug loss after the full 24 hours in all solutions. Hydrocortisone was also stable in the sodium chloride 0.9%, dextrose 5%, and Ringer's injection, lactated with about a 2% drug loss.

However, in Elliott's B solution, hydrocortisone was significantly less stable, with a 6% loss in the 25-mg concentration over 24 hours. The 15-mg concentration was worse, with a 5% loss in 10 hours and a 13% loss in 24 hours. The higher pH of Elliott's B solution and the lower concentration of hydrocortisone may have been factors in this increased decomposition. All mixtures were physically compatible during this study, but a precipitate formed after several days of storage.<sup>819</sup>

Methotrexate sodium (Lederle) 2 mg/mL diluted in Elliott's B solution (Orphan Medical) was packaged as 20 mL in 30-mL glass vials and 20-mL plastic syringes (Becton Dickinson) with Red Cap (Burron) Luer-Lok syringe tip caps. The solution was physically compatible and chemically stable exhibiting little loss during storage for 48 hours at 4 and 23°C.<sup>1976</sup>

Bacterially contaminated intrathecal solutions can pose very grave risks. Consequently, intrathecal solutions should be administered as soon as possible after preparation.<sup>328</sup>

### **Syringes**

Methotrexate (Lederle) 50 mg/mL was stable for up to 8 months when stored in Monoject or Plastipak plastic syringes at 25°C. Because of possible alteration in water vapor permeability, use of Sabre and Steriseal plastic syringes is limited to 70 days at 25°C.<sup>1280</sup>

Methotrexate sodium (Lederle) 2.5 mg/mL was repackaged into 10-mL plastic syringes (Becton Dickinson) and stored at 4 and 25°C for 7 days. No loss of methotrexate was found. Furthermore, no contaminants from the syringes were observed.<sup>1913</sup>

### **Sorption**

Methotrexate sodium 22.5 mg/100 mL and 12 g/500 mL in both dextrose 5% and sodium chloride 0.9% in PVC containers (Macoflex, Macopharma) exhibited no sorption loss during 30 days of storage at 4°C protected from light. Simulated infusion of methotrexate sodium 2.25 g/500 mL in dextrose 5% and sodium chloride 0.9% over 24 hours through opaque PVC infusion sets (Perfecran, Fandre) also showed no sorption loss to the PVC tubing.<sup>1867</sup>

Methotrexate sodium (Medac) 0.36 mg/mL in dextrose 5% and in sodium chloride 0.9% exhibited little or no loss due to sorption in polyethylene, PVC, and glass containers over 72 hours at room and refrigeration temperatures.<sup>2420 2430</sup>

### **Central Venous Catheter**

Methotrexate sodium (Immunex) 2.5 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

### Solution Compatibility

#### Methotrexate sodium

# Methotrimeprazine Hydrochloride

AHFS 28:24.92

## Levomepromazine Hydrochloride

### Products

Methotrimeprazine hydrochloride is available in 1-mL ampuls as a 25-mg/mL (2.5% w/v) solution. The injection also contains ascorbic acid, sodium sulfite, and sodium chloride in water for injection.<sup>38 115</sup>

### pH

From 3 to 5.<sup>17</sup>

### Osmolality

Methotrimeprazine hydrochloride injection is an isotonic solution.<sup>38 115</sup>

### Trade Name(s)

Nozinan

### Administration

Methotrimeprazine hydrochloride is administered by intramuscular injection or intravenously after dilution with an equal volume of sodium chloride 0.9% immediately before use. It may also be given by continuous subcutaneous infusion diluted with the appropriate volume of sodium chloride 0.9%.<sup>38 115</sup>

### Stability

Methotrimeprazine hydrochloride injection is a clear, colorless solution. It should be stored at controlled room temperature and protected from light. On exposure to light, methotrimeprazine hydrochloride rapidly develops a pink or yellow discoloration; discolored solutions should be discarded. The drug is incompatible with alkaline solutions.<sup>38 115</sup>

# Methyldopate Hydrochloride

AHFS 24:08.16

## Products

Methyldopate hydrochloride is available as a 50-mg/mL solution in 5-mL single-use vials.<sup>3009</sup> Each mL of solution also contains citric acid, anhydrous 5 mg, sodium bisulfite 3.2 mg, monothio-glycerol 2 mg, methylparaben 1.5 mg, edetate disodium 0.5 mg, propylparaben 0.2 mg, and sodium hydroxide and/or hydrochloric acid to adjust the pH in water for injection.<sup>3009</sup>

## pH

From 3 to 4.2.<sup>17</sup>

## Administration

Methyldopate hydrochloride should be diluted and administered by intravenous infusion.<sup>3009</sup> Intramuscular and subcutaneous injections are *not* recommended due to erratic absorption.<sup>3020</sup> The appropriate dose should be added to 100 mL of dextrose 5%;<sup>3009</sup> alternatively, the dose may be administered as 100 mg/10 mL in dextrose 5%.<sup>3009</sup> The diluted dose should be slowly infused over 30 to 60 minutes.<sup>3009</sup>

## Stability

Intact vials should be stored at controlled room temperature.<sup>3009</sup> In aqueous solutions, the drug is most stable at acid to neutral pH. Oxidation of the catechol ring is the most important degradation process. The rate of such oxidation increases with increasing oxygen supply, increasing pH, and decreasing drug concentration.<sup>1072</sup>

The pH of infusion solutions containing methyldopate hydrochloride tends to be 7 or less, even when alkaline intravenous infusion solutions are used.<sup>3021</sup> It has been suggested that drugs poorly soluble in acidic media, such as barbiturate salts, be mixed cautiously with methyldopate hydrochloride since its acidity imparts some buffer capacity to intravenous admixtures. Furthermore, it should not be used with drugs known to be acid labile.<sup>23</sup>

Methyldopate hydrochloride oxidation is facilitated in alkaline solutions, yielding inactive, dark-colored compounds.<sup>23 436</sup> At pH 7.8, more than a 5% loss occurred over 24 hours.<sup>437</sup>

# Methylene Blue

AHFS 92:12

## Products

Methylene blue (ProveyBlue, American Regent) is available in 10-mL single-use ampuls.<sup>3156</sup> Each mL of solution contains 5 mg of methylene blue in water for injection.<sup>3156</sup>

Methylene blue (Akorn) also is available in single-use vials containing 1 or 10 mL of the injection solution.<sup>3158</sup> Each mL of solution contains 10 mg of methylene blue in water for injection and hydrochloric acid and/or sodium hydroxide to adjust the pH when necessary.<sup>3158</sup>

## Tonicity

The 5-mg/mL methylene blue solution (ProveyBlue) is hypotonic.<sup>3156</sup>

## pH

The 5-mg/mL methylene blue solution (ProveyBlue) has a pH ranging from 3 to 4.5.<sup>3156</sup>

## Osmolality

The 5-mg/mL methylene blue solution (ProveyBlue) has an osmolality of 10 to 15 mOsm/kg.<sup>3156</sup>

## Trade Name(s)

ProveyBlue

## Administration

Methylene blue is administered intravenously very slowly over a period of several minutes<sup>3158</sup> or over 5 to 30 minutes.<sup>3156</sup> Patent venous access should be confirmed prior to administration.<sup>3156</sup> Methylene blue should *not* be administered subcutaneously<sup>3156</sup> or intrathecally,<sup>3158</sup> intraspinal injection is contraindicated.<sup>3158</sup>

The manufacturer of ProveyBlue states that the drug may be diluted prior to administration in 50 mL of dextrose 5% in order to avoid local pain, particularly in pediatric patients.<sup>3156</sup>

## Stability

Methylene blue injection is a clear, dark blue solution.<sup>3156</sup> Intact ampuls and vials should be stored at controlled room temperature.<sup>3156</sup> <sup>3158</sup> The manufacturer of ProveyBlue states that ampuls should be stored in the original container to protect from light and that the drug should not be refrigerated or frozen.<sup>3156</sup>

Methylene blue injection solution should be visually inspected for particulate matter and discoloration prior to administration.<sup>3156</sup> Any unused portion of the solution should be discarded.<sup>3156</sup>

Solutions of methylene blue diluted in dextrose 5% should be used immediately following preparation.<sup>3156</sup> Sodium chloride 0.9% should not be mixed with methylene blue as chloride has been shown to reduce the solubility of the drug.<sup>3156</sup>

## Compatibility Information

# Methylergonovine Maleate

AHFS 76:00

## Products

Methylergonovine maleate 0.2 mg/mL is available in 1-mL ampuls.<sup>3299</sup> Each mL of solution also contains maleic acid 0.1 mg and sodium chloride 7 mg in water for injection.<sup>3299</sup>

## pH

From 2.7 to 3.5.<sup>17</sup>

## Trade Name(s)

Methergine

## Administration

Methylergonovine maleate is administered intramuscularly.<sup>3299</sup> The drug also may be administered intravenously slowly over no less than 1 minute, in combination with careful blood pres-

sure monitoring, if intravenous administration is considered essential as a life-saving measure; it should *not* be administered routinely by the intravenous route.<sup>3299</sup> Administration of methylergonovine maleate by intra-arterial or periarterial injection must be strictly avoided.<sup>3299</sup>

## Stability

Methylergonovine maleate injection is a clear, colorless solution.<sup>3299</sup> Intact ampuls should be stored under refrigeration at 2 to 8°C and protected from light.<sup>3299</sup> The product should be inspected visually for particulate matter and discoloration prior to administration.<sup>3299</sup>

To prevent inadvertent administration of methylergonovine maleate to newborn infants, the ampuls should be stored separately from medications intended for neonatal administration.<sup>3299</sup>

## Methylprednisolone Acetate

AHFS 68:04

### Products

Methylprednisolone acetate is an injectable suspension that is available in 20-, 40-, and 80-mg/mL concentrations in 5- and 10-mL multiple-dose vials. Each mL contains<sup>1(3/03)</sup>:

Component	Concentration/mL		
	20 mg	40 mg	80 mg
Methylprednisolone acetate	20 mg	40 mg	80 mg
Polyethylene glycol 3350	29.5 mg	29.1 mg	28.2 mg
Polysorbate 80	1.97 mg	1.94 mg	1.88 mg
Monobasic sodium phosphate	6.9 mg	6.8 mg	6.59 mg
Dibasic sodium phosphate	1.44 mg	1.42 mg	1.37 mg
Benzyl alcohol	9.3 mg	9.16 mg	8.88 mg
Sodium chloride	to adjust tonicity	to adjust tonicity	to adjust tonicity
Sodium hydroxide and/or hydrochloric acid	qs	qs	qs

Methylprednisolone acetate is also available at concentrations of 40- and 80-mg/mL in 1-mL single-dose vials. Each mL contains<sup>1(3/03)</sup>:

Component	Concentration/mL	
	40 mg	80 mg
Methylprednisolone acetate	40 mg	80 mg
Polyethylene glycol 3350	29 mg	28 mg
Myristyl-gamma-picolinium chloride	0.195 mg	0.189 mg
Sodium chloride	to adjust tonicity	to adjust tonicity
Sodium hydroxide and/or hydrochloric acid	qs	qs

### pH

From 3.5 to 7.0.<sup>1(3/03)</sup>

### Trade Name(s)

Depo-Medrol

### Administration

Methylprednisolone acetate is administered by intramuscular, intra-articular, intrasynovial, soft tissue, and intralesional injection without dilution. The drug is a suspension that must not be administered intravenously.<sup>1(3/03)</sup>

### Stability

The intact vials should be stored at controlled room temperature.<sup>1(3/03)</sup>

## Compatibility Information

# Methylprednisolone Sodium Succinate

AHFS 68:04

## Products

Methylprednisolone sodium succinate is available in 40-mg (1-mL), 125-mg (2-mL), 500-mg (4-mL), and 1-g (8-mL) dual-chamber containers and 500-mg (8-mL), 1-g (16-mL), and 2-g (30.6-mL) vials with and without diluent. Monobasic sodium phosphate anhydrous, dibasic sodium phosphate dried, and lactose in the 40-mg size are also present. Use only the special diluent or bacteriostatic water for injection with benzyl alcohol to reconstitute the vials. The reconstituted solutions contain the methylprednisolone equivalent (as sodium succinate) of 40, 62.5, 125, or 65.4 mg/mL depending on the vial size and reconstitution volume used.<sup>1(7/04)</sup>

## pH

The pH is adjusted to 7 to 8.<sup>1(7/04)</sup> 4

## Osmolarity

The osmolarities of the 40-, 62.5-, 125-, and 65.4-mg/mL concentrations are 500, 400, 440, and 420 mOsm/L, respectively.<sup>1(7/04)</sup>

## Osmolality

The osmolality of methylprednisolone sodium succinate was calculated for the following dilutions:<sup>1054</sup>

Diluent	Osmolality (mOsm/kg)	
	50 mL	100 mL
500 mg		
Dextrose 5%	291	275
Sodium chloride 0.9%	317	301
1 g		
Dextrose 5%	318	292
Sodium chloride 0.9%	345	319

## Sodium Content

Each gram of methylprednisolone sodium succinate contains 2.01 mEq of sodium.<sup>846</sup>

## Trade Name(s)

A-MethaPred, Solu-Medrol

## Administration

Methylprednisolone sodium succinate may be administered by intramuscular and direct intravenous injection and by intermittent or continuous intravenous infusion.<sup>1(7/04)</sup> 4 Direct intravenous injection should be performed over at least 1 minute<sup>4</sup> or over several minutes. High-dose therapy is given intravenously over at least 30 minutes.<sup>1(7/04)</sup>

## Stability

Intact vials should be stored at controlled room temperature between 20 and 25°C and protected from light. Reconstituted solutions also should be stored between 20 and 25°C and should be used within 48 hours.<sup>1(7/04)</sup>

The drug is subject to both ester hydrolysis and acyl migration. Degradation products include free methylprednisolone, succinate, and methylprednisolone-17-succinate.<sup>1072</sup> Gross decomposition may result in insoluble free methylprednisolone.<sup>2426</sup> The solution should not be used unless it is clear and free of particulate matter.<sup>4</sup>

Methylprednisolone sodium succinate (Upjohn) diluted to a concentration of 4 mg/mL with sterile water for injection and packaged in glass vials was evaluated for stability. The samples stored at 22°C lost 10% in 24 hours while those stored at 4°C lost 6% in 7 days and 17% in 14 days.<sup>1938</sup>

## pH Effects

The minimum rate of hydrolysis occurs at pH 3.5. Between pH 3.4 and 7.4, acyl migration is the dominant effect.<sup>1501</sup>

## Freezing Solutions

Reconstituted methylprednisolone sodium succinate (Upjohn) 125 mg/2 mL, when stored frozen, exhibited no loss over 4 weeks.<sup>69</sup>

When stored frozen at -20°C, methylprednisolone sodium succinate (Upjohn) 500 mg/108 mL in sodium chloride 0.9% in polyvinyl chloride (PVC) bags exhibited no loss after 12 months followed by microwave thawing. Furthermore, the solution was physically compatible.<sup>1612</sup>

## Syringes

Methylprednisolone sodium succinate (Pharmacia & Upjohn) 10 mg/mL in sodium chloride 0.9% was packaged in 10-mL polypropylene syringes (Becton Dickinson) and 12-mL polypropylene syringes (Monoject) and stored at 5 and 25°C. The drug solutions remained clear, and about 10% loss occurred in 7 days at 25°C and about 4% loss in 21 days at 5°C. The losses were comparable to the drug solution stored in a glass flask, indicating sorption to syringe components did not occur.<sup>2340</sup>

## Central Venous Catheter

Methylprednisolone sodium succinate (Abbott) 5 mg/mL in dextrose 5% was found to be compatible with the ARROW-g+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>d</sup> Tested in bacteriostatic sodium chloride 0.9% preserved with benzyl alcohol 0.9%.

<sup>e</sup> Tested in either dextrose 5% or in sodium chloride 0.9%, but the report did not specify which solution.

<sup>f</sup> Tested in a 1:1 mixture of (1) D5W and D5½S with and without KCl 20 mEq/L, and also (2) D10½S with and without KCl 20 mEq/L, and also (3) D5W and TPN #274 (see Appendix).

<sup>g</sup> Tested in Ringer's injection, lactated.

<sup>h</sup> Lyophilized formulation tested.

<sup>i</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>j</sup> Tested in sterile water for injection.

<sup>k</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>l</sup> Piperacillin component. Piperacillin in an 8:1 fixed-ratio concentration with tazobactam.

<sup>m</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>n</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>o</sup> Test performed using the formulation WITH edetate disodium.

<sup>p</sup> Salt not specified.

## Additional Compatibility Information

### Infusion Solutions

Solution haziness was reported for methylprednisolone sodium succinate admixtures in intravenous fluids.<sup>702 758</sup> Changes in the manufacturing process for bulk methylprednisolone sodium succinate powder have resulted in substantial improvements in admixture clarity and absence of the haze formation that developed previously in solutions of Solu-Medrol.<sup>670 702</sup>

In a study of the turbidity produced by methylprednisolone sodium succinate (Abbott) 500 mg to 30 g/L, turbidity was substantially higher in dextrose 5% than in sodium chloride 0.9%.<sup>758</sup> Another important factor was the concentration of methylprednisolone sodium succinate. Turbidity was generally higher at intermediate concentrations (2 to 15 g/L) than at low (300 mg/L) or high (20 g/L) concentrations.<sup>758</sup>

These differences in the development of turbidity cannot be explained by simple increased ester hydrolysis due to differing pH values and drug concentrations. Rather, the solubility of free methylprednisolone in various concentrations of methylprednisolone sodium succinate has been suggested as the primary factor. The solubility of free methylprednisolone is increased as the concentration of the sodium succinate ester increases. The increased solubilization is believed to overshadow increased formation of free methylprednisolone in concentrations over 10 g/L, preventing or minimizing precipitation and turbidity. Differences in turbidity between the drug in dextrose 5% and sodium chloride 0.9% are believed to result primarily from the electrolyte content of sodium chloride 0.9% and, to a much lesser extent, the pH of the dextrose admixtures. These differences are presumed to affect the solubilizing capacity and reactivity of the ester.<sup>758</sup>

### Other Drugs

The compatibility of methylprednisolone sodium succinate (Upjohn) with several drugs added to auxiliary medication infusion units has been studied. Primary admixtures were prepared by adding various drugs to dextrose 5%, dextrose 5% in sodium chloride 0.9%, and Ringer's injection, lactated. Up to 100 mL of the primary admixture was added along with methylprednisolone sodium succinate (Upjohn) to the auxiliary medication infusion unit with the following results:<sup>329</sup>

Methylprednisolone Sodium Succinate	Primary Solution	Result
	<i>Aminophylline 500 mg/L</i>	
500 mg	D5S, D5W qs 100 mL	Clear solution for 24 hr
500 mg	LR qs 100 mL	Clear solution for 24 hr
500 mg	Added to 100 mL LR	Clear solution for 1 hr
1000 mg	D5W qs 100 mL	Yellow solution, clear for 24 hr

Methylprednisolone Sodium Succinate	Primary Solution	Result
1000 mg	D5S qs 100 mL	Yellow solution, clear for 6 hr
1000 mg	Added to 100 mL D5S	Yellow solution, clear for 24 hr
1000 mg	LR qs 100 mL or added to 100 mL LR	Yellow solution, clear for 4 hr
2000 mg	D5S, D5W, LR qs 100 mL	Yellow solution, clear for 24 hr
	<i>Heparin Sodium 10,000 units/L</i>	
500 mg	D5S, D5W qs 100 mL	Clear solution for 24 hr
500 mg	LR qs 100 mL or added to 100 mL LR	Clear solution for 6 hr
1000 mg	D5S, D5W qs 100 mL	Clear solution for 6 hr
1000 mg	Added to 100 mL D5W	Clear solution for 24 hr
1000 mg	LR qs 100 mL or added to 100 mL LR	Clear solution for 4 to 6 hr
2000 mg	D5W qs 100 mL	Clear solution for 6 hr
2000 mg	D5S, LR qs 100 mL	Clear solution for 24 hr
	<i>Potassium Chloride 40 mEq/L</i>

# Metoclopramide Hydrochloride

AHFS 56:32

## Products

Metoclopramide hydrochloride is available in 2-mL ampuls and 2-, 10-, and 30-mL vials. Each mL of solution contains metoclopramide (as the hydrochloride) 5 mg with sodium chloride 8.5 mg and hydrochloric acid and/or sodium hydroxide, if necessary, in water for injection.<sup>1(5/05)</sup>

## pH

From 4.5 to 6.5.<sup>1(5/05)</sup> Metoclopramide hydrochloride 1.25, 2.22, and 3.75 mg/mL in sodium chloride 0.9% had pH values of 4.4, 4.1, and 4, respectively.<sup>2161</sup>

## Osmolality

The osmolality of metoclopramide hydrochloride 5 mg/mL was determined to be 280 mOsm/kg.<sup>1233</sup> Metoclopramide hydrochloride 1.25, 2.22, and 3.75 mg/mL in sodium chloride 0.9% had osmolalities of 285, 286, and 294 mOsm/kg, respectively.<sup>2161</sup>

## Trade Name(s)

Reglan

## Administration

Metoclopramide hydrochloride is administered by intramuscular injection, by direct intravenous injection undiluted slowly over 1 or 2 minutes for 10 mg doses of drug, or by intermittent intravenous infusion over 15 minutes diluted in 50 mL of compatible diluent for larger doses.<sup>1(5/05) 4</sup>

## Stability

Metoclopramide hydrochloride injection is a clear, colorless solution; it should be stored at controlled room temperature and protected from freezing. The drug is stable over a pH range of 2 to 9. Metoclopramide hydrochloride is photosensitive; protection from light for the product during storage has been recommended.<sup>4</sup> However, the manufacturer no longer recommends light protection for dilutions under normal lighting conditions, stating that they may be stored up to 24 hours.<sup>1(5/05)</sup>

## Compatibility Information

### Solution Compatibility

#### Metoclopramide HCl

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Amino acids 2.75%, dextrose 25%, electrolytes	TR	RB	5 and 20 mg	Metoclopramide chemically stable for 72 hr at room temperature	854	C
Dextrose 5% in sodium chloride 0.45%				Compatible for 48 hr at room temperature	1(5/05)	C
Dextrose 5% in sodium chloride 0.45%	TR <sup>a</sup>	RB	200 mg	Physically compatible with 2% loss in 24 hr at 25°C exposed to normal room light	1167	C

## Freezing Solutions

Undiluted metoclopramide hydrochloride (Robins) 5 mg/mL packaged as 3 mL in plastic infusion-pump syringes (MiniMed) fitted with Luer-Lok tip caps (Burron) exhibited microprecipitation that did not redissolve upon warming to room temperature when stored frozen at -20°C for as little as 1 day. The precipitate was not visible with the unaided eye. Freezing is not an acceptable storage method for undiluted metoclopramide hydrochloride injection.<sup>2001</sup>

## Syringes

Undiluted metoclopramide hydrochloride (Robins) 5 mg/mL was packaged as 3 mL in plastic infusion-pump syringes (MiniMed) fitted with Luer-Lok tip caps (Burron). Stored for 7 days at 32°C to simulate wearing a portable infusion pump close to the body, metoclopramide hydrochloride was physically stable and little loss occurred. At 23°C, metoclopramide hydrochloride was physically and chemically stable for up to 60 days with little loss occurring. However, large quantities of subvisible particulates formed after that time, making the drug unsuitable for use. Stored under refrigeration at 4°C, metoclopramide hydrochloride remained both physically and chemically stable for up to 90 days.<sup>2001</sup>

Metoclopramide hydrochloride (Solopak) 2.5 mg/mL in sodium chloride 0.9% packaged in polypropylene syringes (Sherwood) was physically stable and exhibited little or no loss in 24 hours stored at 4 and 23°C.<sup>2199</sup>

## Central Venous Catheter

Metoclopramide hydrochloride (Abbott) 0.5 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

# Metoprolol Tartrate

AHFS 24:24

## Products

Metoprolol tartrate is available in 5-mL ampuls, vials, and syringe cartridges.<sup>3542 3543</sup> Each mL of solution contains 1 mg of metoprolol tartrate and 9 mg of sodium chloride.<sup>3542</sup>

## pH

The pH of the injection ranges from 5 to 8.<sup>17</sup>

## Administration

Metoprolol tartrate is administered intravenously.<sup>3542</sup>

## Stability

Metoprolol tartrate injection should be stored at controlled room temperature in the original carton and protected from light and freezing.<sup>3542</sup>

Metoprolol tartrate under simulated summer conditions in paramedic vehicles was exposed to temperatures ranging from 26 to 38°C over 4 weeks. Analysis found no loss of the drug under these conditions.<sup>2562</sup>

# Metronidazole

AHFS 8:30.92

## Products

Metronidazole 5 mg/mL is available as a ready-to-use solution in 100-mL (500-mg) single-dose polyvinyl chloride (PVC) plastic bags. No dilution or buffering is required. Each bag also contains dibasic sodium phosphate 48 mg, citric acid anhydrous 23 mg, and sodium chloride 790 mg in water for injection.<sup>1(6/08)</sup>

## pH

Metronidazole has a pH of 5.5 (ranging from 4.5 to 7).<sup>1(6/08)</sup> 17

## Osmolarity

Metronidazole has an osmolarity of 310 mOsm/L.<sup>1(6/08)</sup>

## Sodium Content

Metronidazole contains 14 mEq of sodium from the excipients per 500 mg of metronidazole.<sup>1(6/08)</sup> 4

## Administration

Metronidazole is administered by continuous intravenous infusion or by intermittent intravenous infusion over 1 hour.<sup>1(6/08)</sup> 4

## Stability

Metronidazole is a clear, colorless, ready-to-use solution that should be stored at controlled room temperature and protected

from light. It should not be stored under refrigeration.<sup>1(6/08)</sup> 4 Refrigeration may result in crystal formation. However, the crystals redissolve on warming to room temperature.<sup>1115</sup>

## Light Effects

Prolonged exposure to light will cause a darkening of the product.<sup>4</sup> However, most manufacturers indicate that short-term exposure to normal room light does not adversely affect metronidazole stability. Direct sunlight should be avoided.<sup>1115</sup>

## Sorption

Metronidazole was shown not to exhibit sorption to PVC bags and tubing, polyethylene tubing, Silastic tubing, and polypropylene syringes.<sup>536 606</sup>

## Central Venous Catheter

Metronidazole (Baxter) 5 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Mexiletine Hydrochloride

AHFS 24:04.04.08

### Products

Mexiletine hydrochloride is available as a 25-mg/mL solution in 10-mL (250-mg) ampuls. The product also contains sodium chloride and water for injection.<sup>38</sup>

### Trade Name(s)

Mexitil

### Administration

Mexiletine hydrochloride is administered intravenously. It should never be given as a bolus. A loading dose is given by intravenous injection at a rate of 1 mL (25 mg) per minute. This is

followed by intravenous infusion of a 500-mg/500 mL (1-mg/mL) dilution in a suitable infusion solution. The initial infusion rate of the first 250 mL of the admixture is 4 mL/min over the first hour followed by infusion of the next 250 mL at 2 mL/min over the next two hours. Maintenance is performed using a 250-mg/500 mL (0.5-mg/mL) dilution administered at a rate of 1 mL/min.<sup>38</sup>

### Stability

Mexiletine hydrochloride injection is a clear, colorless solution that should be stored below 25°C and protected from light. Dilutions for infusion are stable for up to eight hours.<sup>38</sup>

## Compatibility Information

### Solution Compatibility

#### Mexiletine HCl

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I

## Micafungin Sodium

AHFS 8:14.16

### Products

Micafungin sodium is available in vials containing 50 and 100 mg of drug with lactose 200 mg and citric acid and/or sodium hydroxide added during manufacturing to adjust pH.<sup>2893</sup> Reconstitute the 50- or 100-mg vials with 5 mL of sodium chloride 0.9% or dextrose 5%, resulting in solutions containing micafungin sodium 10 or 20 mg/mL, respectively.<sup>2893</sup> Diluents containing a bacteriostatic agent should not be used for reconstitution.<sup>2893</sup> To minimize foaming, gently swirl the vials to dissolve the contents.<sup>2893</sup> Do not shake vigorously.<sup>2893</sup>

### pH

From 5 to 7.<sup>2893</sup>

### Trade Name(s)

Mycamine

### Administration

Micafungin sodium is diluted in 100 mL of sodium chloride 0.9% or dextrose 5% and administered by intravenous infusion over 1 hour.<sup>2893</sup> Existing infusion lines should be flushed with sodium chloride 0.9% prior to starting the micafungin sodium infusion.<sup>2893</sup>

### Stability

Store intact vials at controlled room temperature.<sup>2893</sup> When reconstituted as directed, the manufacturer indicates that micafungin sodium is stable for up to 24 hours at room temperature in the original container.<sup>2893</sup> However, the drug does not contain a preservative, and the manufacturer recommends discarding partially used vials.<sup>2893</sup> Micafungin sodium diluted for infusion is stable for up to 24 hours at room temperature when protected from light.<sup>2893</sup>

### Light Effects

The manufacturer states that micafungin sodium dilutions should be protected from light but that covering tubing and drip chambers is not necessary.<sup>2893</sup>

### Syringes

Micafungin sodium (Astellas) reconstituted with and further diluted in sodium chloride 0.9% to a concentration of 0.5 or 1 mg/mL and stored in 3 different polypropylene syringes demonstrated physical and chemical stability for 15 days stored at 25°C with 60% relative humidity in the dark.<sup>3273</sup>

# Midazolam Hydrochloride

**AHFS 28:24.08**

## Products

Midazolam hydrochloride is available at concentrations equivalent to midazolam 1 and 5 mg/mL in packages containing 1, 2, 5, or 10 mL of solution.<sup>3206 3590 3591 3592</sup> The drug also is available in a 100-mL pharmacy bulk package at a concentration equivalent to midazolam 5 mg/mL.<sup>3250</sup> Formulations generally also contain sodium chloride 0.8%.<sup>3206 3250 3590 3591 3592</sup> Some formulations contain disodium edetate 0.01%, with or without benzyl alcohol 1%.<sup>3206 3250 3590</sup> Preservative-free formulations of midazolam hydrochloride also are available.<sup>3591 3592</sup> The pH of both the preservative-containing and preservative-free formulations of the injection is adjusted with hydrochloric acid and, if necessary, sodium hydroxide.<sup>3206 3250 3590 3591 3592</sup>

Midazolam hydrochloride (Seizalam) also is available at a concentration equivalent to midazolam 5 mg/mL in multidose vials containing 10 mL labeled only for intramuscular administration.<sup>3593</sup> Each mL also contains sodium chloride 0.8%, disodium edetate 0.01%, and benzyl alcohol 1%.<sup>3593</sup> The pH of the injection is adjusted with hydrochloric acid and, if necessary, sodium hydroxide.<sup>3593</sup>

## pH

The pH of the injection (Hospira) is approximately 3,<sup>3590 3591 3592</sup> pH ranges including 3 also have been reported for other products.<sup>3206 3250</sup>

The pH of the injection (Seizalam) labeled only for intramuscular administration is approximately 3.<sup>3593</sup>

Midazolam (Roche) 0.625, 1.25, and 1.67 mg/mL in sodium chloride 0.9% had pH values of 3.6, 3.4, and 3.4, respectively.<sup>2161</sup>

## Osmolality

Midazolam (Roche) 0.625, 1.25, and 1.67 mg/mL in sodium chloride 0.9% had osmolalities of 274, 262, and 259 mOsm/kg, respectively.<sup>2161</sup>

## Trade Name(s)

Versed, Seizalam

## Administration

Midazolam hydrochloride is administered intramuscularly by injection deep into a large muscle mass or intravenously by slow intermittent injection in incremental doses or by continuous infusion.<sup>3590 3591 3592</sup> Use of the 1-mg/mL concentration or dilution of the 1- or 5-mg/mL concentration is recommended to facilitate slower injection.<sup>3590 3591 3592</sup> While the 5-mg/mL concentration is recommended for dilution for continuous intravenous infusion, both the 1- and 5-mg/mL concentrations may be diluted with sodium chloride 0.9% or dextrose 5%.<sup>3590 3591 3592</sup>

Administration of midazolam hydrochloride by rapid intravenous injection should be avoided, especially in neonatal and non-neonatal pediatric populations.<sup>3590 3591 3592</sup>

Intra-arterial injection and extravasation should be avoided.<sup>3590 3591 3592</sup>

Midazolam hydrochloride (Seizalam) is labeled only for intramuscular administration, specifically into the mid-outer thigh (i.e., vastus lateralis muscle).<sup>3593</sup>

## Stability

Intact vials and cartridges should be stored at controlled room temperature.<sup>3590 3591 3592 3593</sup>

## pH Effects

Midazolam hydrochloride is highly water soluble at pH 4 or less; at higher pH values, increased lipid solubility occurs.<sup>1145</sup> The rate of photodecomposition increases with increasing pH from 1.3 to 6.4.<sup>1944</sup>

## Light Effects

Exposure of the commercially available injection (Roche) to sunlight for 4 months resulted in the yellowing of the solution in 1 month and a midazolam loss of about 8% in 4 months.<sup>1944</sup>

## Syringes

In 2015, reports of decreased potency of certain drugs (e.g., midazolam hydrochloride) stored in Becton Dickinson syringes for extended periods (i.e., exceeding 24 hours) were confirmed by the manufacturer of these syringes; the cause of this change was later identified to be the inclusion of an alternate rubber stopper in the plunger of certain product lots of syringes.<sup>3029 3036 3037 3039 3041 3042</sup> Decreased potency was not observed when the syringes were filled and used promptly.<sup>3037</sup> Use of the alternate stopper was later discontinued and use of the primary stopper in such syringes was resumed; however, Becton Dickinson states that its general-use syringes are cleared by FDA for immediate use in fluid aspiration and injection and that such syringes, regardless of the stopper material, have not been cleared by FDA for use as a closed-container system.<sup>3391</sup>

Midazolam hydrochloride (Roche) prepared at a midazolam concentration of 2 mg/mL in sodium chloride 0.9% was packaged as 3 mL in 10-mL polypropylene infusion pump syringes (Pharmacia Deltec). Little or no loss occurred during 10 days of storage at 5 and 30°C.<sup>1967</sup>

Midazolam hydrochloride (Roche) prepared at a midazolam concentration of 3 mg/mL in sodium chloride 0.9% exhibited no visual changes and had losses of 6.5% at 20°C and 8.7% at 32°C in polypropylene syringes (Terumo) and of 8.9% at 32°C in glass vials after 13 days.<sup>1595</sup>

The stability of midazolam (salt form unspecified) 1 mg/mL repackaged in polypropylene syringes was evaluated. Little change in concentration was found after 4 weeks of storage at room temperature not exposed to direct light.<sup>2164</sup>

Midazolam hydrochloride (Roche) at a midazolam concentration of 5 mg/mL was packaged as 10 mL in 12-mL polypropylene syringes (Sherwood). No loss occurred in 36 days stored at 25°C protected from light.<sup>2088</sup>

## Compatibility Information

Test Drug	Mfr	Amt	Mfr	Amt	Remarks	Ref	C/I
Dexamethasone sodium phosphate	DB	2 mg/8 mL	RC	5 mg/8 mL	Diluted in NS. Visually clear. No dexamethasone loss in 48 hr. Midazolam losses were 7% in 48 hr at room temperature	2531	C
Dexamethasone sodium phosphate	DB	4 mg/8 mL	RC	5 mg/8 mL	Diluted in NS. Cloudiness forms immediately	2531	I
Dexamethasone sodium phosphate	DB	4 mg/8 mL	RC	7.5 mg/8 mL	Diluted in NS. Cloudiness forms immediately	2531	I
Dexamethasone sodium phosphate	DB	2 mg/8 mL	RC	7.5 mg/8 mL	Diluted in NS. Crystals form in some samples within 24 hr	2531	I
Diamorphine HCl	EV	10 mg	RC	10 <sup>b</sup> and 75 <sup>c</sup> mg	Visually compatible. 10% diamorphine and no midazolam loss in 15.9 days at 22°C	1792	C
Diamorphine HCl	EV	500 mg	RC	10 <sup>b</sup> and 75 <sup>c</sup> mg	Visually compatible. 10% diamorphine and no midazolam loss in 22.2 days at 22°C	1792	C
Dimenhydrinate	SE	50 mg/1 mL	RC	5 mg/1 mL	White precipitate forms immediately	1145	I
Diphenhydramine HCl	ES	50 mg/1 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Droperidol	JN	2.5 mg/1 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Fentanyl citrate	ES	0.1 mg/2 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Fentanyl citrate	DB	12.5 mcg/mL <sup>a</sup>	RC	0.625 and 0.938 mg/mL <sup>a</sup>	Visually compatible. Little fentanyl loss. 7 and 9% midazolam loss in 7 days at 5 and 22°C, respectively	2202	C
Fentanyl citrate	DB	37.5 mcg/mL <sup>a</sup>	RC	0.625 mg/mL <sup>a</sup>	Visually compatible. No fentanyl loss. 5 and 8% midazolam loss in 7 days at 5 and 22°C, respectively	2202	C
Fentanyl citrate	DB	37.5 mcg/mL <sup>a</sup>	RC	0.938 mg/mL <sup>a</sup>	Visually compatible. Little fentanyl loss. 7 and 9% midazolam loss in 7 days at 5 and 22°C, respectively	2202	C
Fentanyl citrate	DB	33.3 mcg/mL <sup>a</sup>	RC	0.278 and 0.833 mg/mL <sup>a</sup>	Visually compatible. No fentanyl loss. 5 and 7% midazolam loss in 7 days at 5 and 22°C, respectively	2202	C
Fentanyl citrate with metoclopramide HCl	DB AST	1 mg/20 mL 20 mg/4 mL	RC	15 mg/3 mL	Visually compatible with 7% or less loss of each drug in 10 days at 32°C	2268	C
Glycopyrrolate	RB	0.2 mg/1 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Heparin sodium		2500 units/1 mL	RC	15 mg/3 mL	Turbidity or precipitate forms within 5 min	1053	I
Hydromorphone HCl	WB	2 mg/0.5 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Hydroxyzine HCl	ES	100 mg/2 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Meperidine HCl	WB	100 mg/1 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Metoclopramide HCl	RB	10 mg/2 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Metoclopramide HCl with fentanyl citrate	AST DB	20 mg/4 mL 1 mg/20 mL	RC	15 mg/3 mL	Visually compatible with 7% or less loss of each drug in 10 days at 32°C	2268	C
Morphine sulfate	WB	10 mg/1 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Morphine sulfate		5 and 10 mg/1 mL <sup>d</sup>	RC	5 mg/1 mL	Visually compatible. 9% or less morphine and 8% or less midazolam loss in 14 days at 22°C in dark. Microprecipitate may form, requiring filtration	1901	C
Morphine sulfate		5 and 10 mg/1 mL <sup>e</sup>	RC	5 mg/1 mL	Visually compatible. 8% or less morphine and 3% or less midazolam loss in 14 days at 22°C protected from light. Microprecipitate may form, requiring filtration	1901	C

Test Drug	Mfr	Amt	Mfr	Amt	Remarks	Ref	C/I
Nalbuphine HCl	DU	10 mg/1 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Ondansetron HCl	GW	1.33 mg/mL <sup>a</sup>	RC	1.66 mg/mL <sup>a</sup>	Physically compatible. Under 4% ondansetron and under 7% midazolam losses in 24 hr at 4 or 23°C	2199	C
Oxycodone HCl	NAP	200 mg/20 mL	RC	100 mg/20 mL	Visually compatible. Under 4% concentration change in 24 hr at 25°C	2600	C
Pantoprazole sodium	<sup>f</sup>	4 mg/1 mL		5 mg/1 mL	Precipitates immediately	2574	I
Pentobarbital sodium	WY	100 mg/2 mL	RC	5 mg/1 mL	White precipitate forms immediately	1145	I
Prochlorperazine edisylate	SKF	10 mg/2 mL	RC	5 mg/1 mL	White precipitate forms immediately	1145	I
Promethazine HCl	WY	25 mg/1 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Ranitidine HCl	GL	50 mg/2 mL	RC	5 mg/1 mL	White precipitate forms immediately	1145	I
Scopolamine HBr	BW	0.43 mg/0.5 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C
Trimethobenzamide HCl	BE	200 mg/2 mL	RC	5 mg/1 mL	Physically compatible for 4 hr at 25°C	1145	C

<sup>a</sup> Diluted with sodium chloride 0.9%.<sup>b</sup> Diluted with sterile water to 15 mL.<sup>c</sup> Diamorphine hydrochloride constituted with midazolam injection.<sup>d</sup> Morphine sulfate powder dissolved in dextrose 5%.<sup>e</sup> Morphine sulfate powder dissolved in water and sodium chloride 0.9%.<sup>f</sup> Test performed using the formulation WITHOUT edetate disodium.**Y-Site Injection Compatibility (1:1 Mixture)****Midazolam HCl**

<sup>a</sup> Tested in dextrose 5%.

<sup>b</sup> Tested in sodium chloride 0.9%.

<sup>c</sup> Tested in sterile water for injection.

<sup>d</sup> Tested in Ringer's injection, lactated.

<sup>e</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>f</sup> Concentration unspecified.

<sup>g</sup> Concentration expressed in milligrams of phenytoin sodium equivalents (PE) per mL.

<sup>h</sup> Given over three minutes into a heparin infusion run at 1 mL/min.

<sup>i</sup> Tested in dextrose 5% in sodium chloride 0.225%.

<sup>j</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>k</sup> Amoxicillin component. Amoxicillin in a 10:1 fixed-ratio concentration with clavulanic acid.

<sup>l</sup> Trimethoprim component. Trimethoprim in a 1:5 fixed-ratio concentration with sulfamethoxazole.

<sup>m</sup> Not specified whether concentration refers to single component or combined components.

<sup>n</sup> Tested in both dextrose 5% and sodium chloride 0.9%.

<sup>o</sup> Ceftolozane component. Ceftolozane in a 2:1 fixed-ratio concentration with tazobactam.

<sup>p</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

<sup>q</sup> Test performed using the formulation WITH edetate disodium.

<sup>r</sup> As midazolam base rather than the salt.

**Additional Compatibility Information****Other Drugs**

One manufacturer (Hospira) states that midazolam hydrochloride may be administered in the same syringe as atropine sulfate, meperidine hydrochloride, morphine sulfate, and scopolamine hydrobromide.<sup>3590 3591 3592</sup>

## Milrinone Lactate

AHFS 24:04.08

### Products

Milrinone lactate is available as a solution containing the equivalent of milrinone 1 mg/mL in 10-, 20-, and 50-mL single-dose vials. Each mL also contains dextrose, anhydrous, 47 mg in water for injection. Lactic acid or sodium hydroxide may have been used to adjust the pH. The total lactic acid concentration may vary between 0.95 and 1.29 mg/mL. The 1-mg/mL concentration must be diluted for use.<sup>1(9/07)</sup>

Milrinone lactate is also available as a ready-to-use solution in 100- and 200-mL flexible polyvinyl chloride (PVC) containers at a concentration equivalent to milrinone 0.2 mg/mL (200 mcg/mL). The solution has a nominal lactic acid concentration of 0.282 mg/mL and also contains dextrose, anhydrous 49.4 mg/mL.<sup>1(9/07)</sup>

### pH

From 3.2 to 4.<sup>1(9/07)</sup>

### Administration

Milrinone lactate is administered intravenously. For maintenance administration by continuous intravenous infusion, milrinone lactate in vials is diluted in a compatible diluent, usually to 200 mcg/mL. The premixed 200-mcg/mL infusion in flexible plastic containers need not be diluted for use. When milrinone lactate is administered by continuous infusion, the use of a calibrated electronic infusion device is recommended.<sup>1(9/07)</sup>

### Stability

Milrinone lactate solutions are colorless to pale yellow. The 1-mg/mL concentration should be stored at controlled room temperature and protected from freezing. The 0.2-mg/mL concentration in PVC containers should be stored at room temperature of 25°C and should be protected from freezing and exposure to excessive heat. Brief exposure to temperatures up to 40°C does not adversely affect the product.<sup>1(9/07)</sup>

## Compatibility Information

### Solution Compatibility

## Minocycline Hydrochloride

AHFS 8:12.24

### Products

Minocycline hydrochloride is available as a yellow to amber lyophilized powder in single-use vials containing the equivalent of 100 mg of minocycline with 269 mg of magnesium sulfate heptahydrate (2.2 mEq of magnesium) and sodium hydroxide to adjust the pH.<sup>3226</sup>

The 100-mg vial should be reconstituted with 5 mL of sterile water for injection to yield a solution containing minocycline 20 mg/mL.<sup>3226 3269</sup> The reconstituted solution should be further diluted immediately in 100 to 1000 mL of dextrose 5%, dextrose 5% in sodium chloride 0.9%, or sodium chloride 0.9%; alternatively, the reconstituted solution may be diluted in 250 to 1000 mL of Ringer's injection, lactated (see Stability).<sup>3226 3232</sup>

### pH

The pH of the reconstituted solution ranges from 4.5 to 5.<sup>3226</sup> When diluted in a compatible infusion solution, the pH usually ranges from 4.5 to 6.<sup>3226</sup>

### Trade Name(s)

Minocin

### Administration

Minocycline hydrochloride is administered by intravenous infusion over 60 minutes following dilution in a compatible infusion solution.<sup>3226</sup> If a common infusion line is being used to administer other drugs in addition to minocycline hydrochloride, the line should be flushed with a compatible infusion solution prior to and following infusion of minocycline.<sup>3226</sup>

### Stability

Intact vials should be stored at controlled room temperature.<sup>3226</sup>

Upon dilution in an infusion bag containing a compatible solution, minocycline is stable for up to 4 hours at room temperature or up to 24 hours at 2 to 8°C.<sup>3226</sup>

Although minocycline hydrochloride is noted to be stable at certain concentrations in Ringer's injection, lactated, the drug should not be mixed with other calcium-containing solutions, especially neutral or alkaline solutions, due to the potential for precipitation.<sup>3226</sup> Unused portions should be discarded.<sup>3226</sup>

### pH Effects

A precipitate may form if minocycline hydrochloride is diluted in neutral or alkaline solutions.<sup>3226</sup>

# Mitomycin

## AHFS 10:00

### Products

Mitomycin is available in 5-, 20-, and 40-mg vials with mannitol 10, 40, and 80 mg, respectively. Reconstitute the 5-mg vials with 10 mL, the 20-mg vials with 40 mL, and the 40-mg vials with 80 mL of sterile water for injection and shake to aid dissolution. Allow to stand at room temperature if dissolution does not take place immediately. The reconstituted solution contains 500 mcg/mL of mitomycin.<sup>1(10/06) 4</sup>

### pH

From 6 to 8.<sup>4</sup>

### Administration

Mitomycin is administered intravenously through a functioning intravenous catheter. Extravasation should be avoided because cellulitis, ulceration, and sloughing may occur. It has been recommended that mitomycin be administered through the tubing of a running infusion solution to avoid this problem.<sup>1(10/06) 4</sup>

In the event of spills or leaks, Bristol-Myers Squibb recommends the use of sodium hypochlorite 5% (household bleach) or potassium permanganate 1% to inactivate mitomycin.<sup>1200</sup>

### Stability

Intact vials should be stored at controlled room temperature and protected from light. Temperatures exceeding 40°C should be avoided. Reconstituted solutions are stable for two weeks stored under refrigeration or for one week at room temperature.<sup>1(10/06) 4</sup>

Mitomycin (Kyowa) 0.6 and 0.8 mg/mL in water for injection exhibited 10% loss in seven days at 21°C in the dark. When stored at 4°C in the dark, the 0.6-mg/mL concentration lost 7% in seven days. Although exhibiting no loss in 24 hours when stored at 4°C in the dark, the 0.8-mg/mL concentration developed a fine, pink, needle-like precipitate in three days. At a higher concentration of 1 mg/mL in water for injection similar results were obtained. Refrigeration resulted in fine, pink, needle-like precipitate formation in 24 hours. The 1-mg/mL concentration stored at 21°C exposed to fluorescent light exhibited 6% loss in 24 hours and developed the fine, pink, needle-like precipitate in four days. Stored at a higher temperature of 25°C in the dark, losses of 6% in 24 hours and 10% in seven days were found with no precipitate forming.<sup>1503</sup>

### pH Effects

Mitomycin is very stable in solution at a neutral pH but undergoes more rapid decomposition at acidic and basic pH.<sup>1119 1203 1204 1866</sup>

The decomposition is complex and pH dependent, producing different decomposition products in acidic and basic solutions.<sup>1119</sup>

<sup>1283 1284</sup> The pH of maximum stability is approximately pH 7.<sup>1072</sup>

<sup>1203 1204 1379</sup> At pH 7, a 10% mitomycin loss occurs in seven days at room temperature.<sup>1072</sup> At a concentration of 0.05 mg/mL in dextrose 5% buffered to pH 7.8 with a mixture of phosphates, mitomycin was stable for 15 days at room temperature and over 120 days when refrigerated.<sup>1118</sup>

Both pH and storage temperature are important to mitomycin stability. Mitomycin (150 to 600 mcg/mL) stability was tested in pH 6, 7, and 8 buffer solutions. The drug was less stable at pH 6 than at pH 7 and especially pH 8. At pH 6, drug losses of around 96 and 41% occurred at room temperature and under refrigeration, respectively, over 28 days. However, mitomycin was more stable at pH 7 and 8. Drug losses when stored under refrigeration for 28 days were about 10 to 20% in this pH range.<sup>2651</sup>

### Temperature Effects

Heating mitomycin 0.6 mg/mL in sodium chloride 0.9% to 100°C resulted in a 24% drug loss in 30 minutes and a 58% loss in one hour.<sup>1285</sup>

### Freezing Solutions

Mitomycin 0.6 mg/mL in sodium chloride 0.9% crystallized out of solution when frozen at -20°C. The particles did not redissolve after thawing in a microwave oven. Freezing to -30°C, below the eutectic temperature, resulted in no loss of mitomycin during four weeks of storage, microwave thawing, and refreezing at -30°C for another four weeks.<sup>1285</sup>

### Light Effects

The stability of mitomycin is not adversely affected by the presence or absence of normal fluorescent light.<sup>1503</sup>

### Syringes

Mitomycin (Bristol-Myers Squibb) reconstituted to a concentration of 0.5 mg/mL with sterile water was repackaged in 1-mL polypropylene tuberculin syringes (Sherwood). Syringes were stored at both 5 and 25°C protected from light. About 7% mitomycin loss occurred in 11 days at 25°C and about 8% loss in 42 days at 5°C.<sup>2179</sup>

### Filtration

Mitomycin 10 to 75 mcg/mL exhibited little or no loss due to sorption to either cellulose nitrate/cellulose acetate ester (Millex OR) or Teflon (Millex FG) filters.<sup>1415 1416</sup>

# Mitoxantrone Hydrochloride

## AHFS 10:00

### Products

Mitoxantrone hydrochloride is supplied as a concentrate for injection in multidose vials.<sup>2948 2949</sup> The concentrate must be diluted prior to administration.<sup>2948 2949</sup> Each mL of the dark blue aqueous concentrate contains mitoxantrone 2 mg (as the hydrochloride salt), sodium chloride 0.8%, sodium acetate 0.005%, and acetic acid 0.046%.<sup>2948 2949</sup> Some products also contain sodium metabisulfite 0.01%.<sup>2949</sup>

### pH

From 3 to 4.5.<sup>2948 2949</sup>

### Sodium Content

Each mL contains sodium 0.14 mEq.<sup>2948 2949</sup>

### Administration

Mitoxantrone hydrochloride concentrate for injection must be diluted for use.<sup>2948 2949</sup> The drug is administered by intravenous infusion after dilution to at least 50 mL in dextrose 5% or sodium chloride 0.9%.<sup>2948 2949</sup> The drug may be further diluted in dextrose 5%; sodium chloride 0.9%; or dextrose 5% in sodium chloride 0.9%.<sup>2948 2949</sup> Mitoxantrone hydrochloride is administered over about 5 to 15 minutes as a short intravenous infusion or 24 hours by continuous intravenous infusion.<sup>2948 2949</sup> The drug should be administered into the tubing of a freely running intravenous solution of sodium chloride 0.9% or dextrose 5%.<sup>2948 2949</sup> The tubing should be attached to a butterfly needle or other suitable device, inserted preferentially into a large vein.<sup>2948 2949</sup> The drug should not be given over less than 3 minutes.<sup>2948 2949</sup>

Mitoxantrone hydrochloride should *not* be administered by other routes (e.g., subcutaneous, intramuscular, intra-arterial, intrathecal).<sup>2948 2949</sup>

### Stability

Intact vials of the dark blue concentrate for injection should be stored upright at controlled room temperature and protected from freezing.<sup>2948 2949</sup> Refrigeration of the concentrate may cause a precipitate, which redissolves upon warming to room temperature.<sup>72 1369</sup>

The manufacturers indicate that mitoxantrone hydrochloride concentrate remaining in partially used vials may be stored for

up to 7 days at 15 or 20 to 25°C and up to 14 days under refrigeration but should not be frozen.<sup>2948 2949</sup>

Combining heparin with mitoxantrone hydrochloride may result in precipitate formation.<sup>1293 2948 2949</sup>

### pH Effects

The pH range of maximum stability is 2 to 4.5; the solution was unstable when the pH was increased to 7.4.<sup>1379</sup>

### Light Effects

Mitoxantrone hydrochloride is not photolabile. Exposure of the product to direct sunlight for 1 month caused no change in its appearance or concentration.<sup>72 1293</sup>

### Syringes

Mitoxantrone hydrochloride 0.2 mg/mL in sodium chloride 0.9% in polypropylene syringes (Braun Omnifix) is reported to be stable for 28 days at 4 and 20°C.<sup>1564</sup> Mitoxantrone hydrochloride 0.2 mg/mL in water for injection in polypropylene syringes is reported to be stable for 14 days at 4 and 20°C and for 24 hours at 37°C.<sup>1369</sup>

Mitoxantrone hydrochloride (Lederle) 2 mg/mL in glass vials and drawn into 12-mL plastic syringes (Monoject) exhibited no visual changes and little or no loss when stored for 42 days at 4 and 23°C. Potential extractable materials from the syringes were not detectable during the study period.<sup>1593</sup>

### Sorption

Mitoxantrone hydrochloride (Lederle) 1 mg/mL in sodium chloride 0.9% exhibited no loss due to sorption to polyvinyl chloride (PVC) and polyethylene administration lines during simulated infusion at 0.875 mL/hr for 2.5 hours via a syringe pump.<sup>1795</sup>

### Filtration

Although binding of mitoxantrone hydrochloride to filters has been reported,<sup>1249 1415 1416</sup> one manufacturer stated that filtration of mitoxantrone hydrochloride through a 0.22- $\mu$ m filter (Millipore) resulted in no loss.<sup>1293</sup>

Mitoxantrone hydrochloride (Lederle) 1 mg/mL in sodium chloride 0.9%, during simulated infusion at 0.875 mL/hr for 2.5 hours via a syringe pump, exhibited no loss due to sorption to cellulose acetate (Minisart 45, Sartorius), polysulfone (Acrodisc 45, Gelman), and nylon (Posidyne ELD96, Pall) filters.<sup>1795</sup>

## Morphine Sulfate

AHFS 28:08.08

### Products

Morphine sulfate is available in a variety of concentrations (e.g., ranging from 0.5 to 50 mg/mL), packages (e.g., vials, ampuls, cartridges, syringes, patient-controlled analgesia [PCA] vials, auto-injectors), and sizes.<sup>3484 3485 3486 3487 3488 3489</sup>

<sup>3490 3491</sup> Some formulations are preservative free and may be labeled for epidural and intrathecal administration.<sup>3484 3485 3486</sup>

Other morphine products may contain various preservatives, antioxidants, and buffers, including edetate disodium, sodium metabisulfite, benzyl alcohol, and citric acid;<sup>3487 3488 3489 3490 3491</sup> specific product labeling should be consulted for additional formulation details and labeled routes of administration of each product.

Morphine also is available in some countries as the hydrochloride and tartrate salts.

### pH

The pH of many morphine sulfate products falls within the range of 2.5 to 6.5,<sup>3484 3487 3489 3491</sup> with some products exhibiting a more narrow pH range of 2.5 to 4<sup>3488</sup> or a pH of 4.5,<sup>3485 3486</sup> specific product labeling should be consulted for the pH of a specific product.

Morphine sulfate (David Bull) 7.5 mg/mL in sodium chloride 0.9% had a pH of 3.5.<sup>2161</sup>

### Osmolality

Morphine sulfate (David Bull) 7.5 mg/mL in sodium chloride 0.9% had an osmolality of 236 mOsm/kg.<sup>2161</sup>

### Trade Name(s)

Astramorph PF, Duramorph, Infumorph, Mitigo

### Administration

Morphine sulfate may be administered by slow, direct intravenous injection<sup>3488 3490</sup> or by intramuscular<sup>3489 3490</sup> or subcutaneous injection; the drug also may be given by slow intravenous injection or continuous intravenous infusion after dilution.<sup>3491</sup> For continuous intravenous infusion using an infusion pump, one manufacturer recommends a final morphine sulfate concentration of 0.2 to 1 mg/mL in dextrose 5%;<sup>3491</sup> more concentrated solutions also have been used. Some products containing no preservatives may be labeled for intrathecal or epidural administration.<sup>3484 3485 3486</sup>

Some higher-concentration morphine sulfate products (e.g., 10, 25, or 50 mg/mL) are not recommended for subcutaneous, intramuscular, intravenous, or neuraxial injection of individual doses; such products may be labeled for intraspinal administration (with or without dilution) using a continuous microinfusion device<sup>3485 3486</sup> or for continuous intravenous infusion only after dilution using an infusion pump.<sup>3491</sup>

### Stability

Intact containers should be stored in the carton at controlled room temperature and protected from freezing and light.<sup>3484</sup>

<sup>3485 3486 3487 3488 3489 3490 3491</sup> Manufacturers state that the products should not be heat sterilized<sup>3484 3485 3486 3487 3488 3491</sup> or autoclaved.<sup>3490</sup> Morphine sulfate darkens with age and upon prolonged exposure to light;<sup>3488 3490 3491</sup> the injection should not be used if it is darker than pale yellow in color or if is discolored in any other way.<sup>3484 3485 3486 3487 3490 3491</sup>

Undiluted morphine sulfate 10 mg/mL, stored in 100-mL glass vials and polyvinyl chloride (PVC) bags, exhibited no loss in 30 days at 23°C.<sup>1394</sup>

Morphine sulfate (Wyeth) 1 mg/mL in bacteriostatic sodium chloride 0.9% containing benzyl alcohol 0.9%, when stored in glass vials with protection from light, exhibited no loss at 4°C and a 4% loss at 22°C after 91 days.<sup>1583</sup>

Morphine sulfate 15 mg/mL and 2 mg/mL diluted with sterile water for injection stored at 4 and 24°C in 200-mL PVC bags (Baxter) was stable at both temperatures with little loss in 15 days.<sup>1504</sup>

Morphine sulfate under simulated summer conditions in paramedic vehicles was exposed to 26 to 38°C over 4 weeks. No drug loss occurred under these conditions.<sup>2562</sup>

Morphine sulfate 1 mg/mL compounded in sodium chloride 0.9% was packaged in 100-mL polypropylene infusion bags and was autoclaved at 121°C for 20 minutes for sterilization. No visible precipitation appeared and microparticulate levels remained acceptable in all samples when stored at 25°C for 3 years and at 30 and 40°C for 6 months. No evidence of evaporation was found in the samples, and no loss of morphine sulfate occurred in any of the solutions throughout the study. While PVC bags cannot be autoclaved and exhibit excessive loss of water through evaporation upon storage, polypropylene bags can be successfully used for compounding bags of morphine sulfate solutions with 3-year stability for use in patient-controlled analgesia.<sup>2665</sup>

### pH Effects

Morphine sulfate is relatively stable at acidic pH, especially below pH 4, but degradation increases greatly at neutral or basic pH. Degradation is often accompanied by a yellow to brown discoloration in the normally colorless solution.<sup>1072 2170</sup>

Morphine sulfate stability at a low concentration of 2 mg/mL in an admixture with ketamine hydrochloride in sodium chloride 0.9% with the pH adjusted over a range of pH 5.5 to 7.5 was stored at room temperature over 4 days. No difference in physical or chemical drug stability was observed among the samples.<sup>2786</sup>

However, at higher concentrations of morphine at pH values of 6.4 and above, precipitation may occur. Morphine sulfate at about 18 mg/mL mixed with ketamine hydrochloride exhibited a pH near 4.85. Adjusting the pH higher with sodium bicarbonate injection up to pH 5.9 resulted in mixtures that were clear over 24 hours at 21°C. However, adjusting to pH 6.2 resulted in precipitation within 2 hours. Adjusting to pH 6.4 and above resulted in immediate precipitation.<sup>2787</sup>

### Freezing Solutions

Manufacturers state that morphine sulfate products should not be frozen.<sup>3484 3485 3486 3487 3488 3489 3490 3491</sup>

Morphine sulfate (Lilly) 1 and 2 mg/mL in dextrose 5% and sodium chloride 0.9% in PVC bags exhibited no loss during 14 weeks of frozen storage at -20°C.<sup>1286</sup>

### Syringes

In 2015, reports of decreased potency of certain drugs (e.g., morphine sulfate) stored in Becton Dickinson syringes for extended periods (i.e., exceeding 24 hours) were confirmed by the manufacturer of these syringes; the cause of this change was later identified to be the inclusion of an alternate rubber stopper in the plunger of certain product lots of syringes.<sup>3029 3036 3037 3039 3041 3042</sup> Decreased potency was not observed when the syringes were filled and used promptly.<sup>3037</sup> Use of the alternate stopper was later discontinued and use of the primary stopper in such syringes was resumed; however, Becton Dickinson states that its general-use syringes are cleared by FDA for immediate use in fluid aspiration and injection and that such syringes, regardless of the stopper material, have not been cleared by FDA for use as a closed-container system.<sup>3391</sup>

Prefilled into plastic syringes with syringe caps (Braun), morphine sulfate is stated to remain within acceptable limits of degradation for at least 69 days at room temperature.<sup>982</sup>

In another study, less than a 3% loss of morphine sulfate occurred in 12 weeks when stored in plastic syringes at 22°C and exposed to light. A smaller loss occurred when the morphine sulfate was stored at 3°C with light protection.<sup>1287</sup>

Morphine sulfate (Lilly) 1 and 5 mg/mL in dextrose 5% and sodium chloride 0.9% was packaged in 30-mL Plastipak (Becton Dickinson) syringes capped with Monoject (Sherwood) tip caps. Syringes were stored at 23°C in light and dark, 4°C protected from light, and frozen at -20°C protected from light for 12 weeks. Both concentrations at all 3 temperatures were stable for at least 6 weeks when protected from light. However, the samples stored at 23°C exposed to light were stable for 1 week, but developed unacceptable losses after that.<sup>1894</sup>

Morphine sulfate 2 mg/mL in sodium chloride 0.9% was packaged in 50-mL (Becton Dickinson) and 30-mL (Becton Dickinson and Sherwood) polypropylene syringes for use in patient-controlled analgesia and in stoppered glass vials. The samples were stored at room temperature in the dark for 6 weeks. Little loss of morphine sulfate occurred in the 50-mL syringes and the glass vials in 6 weeks. About 5% loss occurred when packaged in both Becton Dickinson and Sherwood 30-mL syringes. Addition

of sodium metabisulfite 0.1% as an antioxidant increased the rate of drug loss up to 10% in 2 weeks.<sup>2040</sup>

Morphine sulfate 5 mg/mL in sodium chloride 0.9% and 50 mg/mL in sterile water for injection and also in sodium chloride 0.9% packaged as 20 mL in 30-mL polypropylene syringes were stored for 60 days at 4°C protected from light and 23°C exposed to normal fluorescent light. Other solutions were stored frozen at -20°C and at elevated temperature of 37°C for 2 days to simulate more extreme conditions during express shipping. Little or no morphine sulfate loss occurred in the 50-mg/mL samples stored for 60 days at 4 and 23°C even though slight yellow discoloration occurred after 30 days. The 5-mg/mL samples stored at 4 and 23°C exhibited about 4 to 5% loss in 60 days. The frozen and 37°C samples exhibited little or no change in morphine sulfate concentration in 2 days. However, samples of the 50-mg/mL concentration stored at -20 and 4°C and samples of the 5-mg/mL concentration stored frozen at -20°C precipitated upon low temperature storage. Although the precipitate redissolved upon warming at 37°C for several hours, large amounts of microparticulates in the tens of thousands per mL remained, possibly shed by the syringe components.<sup>2376</sup>

### Ambulatory Pumps

Walker et al. reported the stability of undiluted morphine sulfate (Sabex) 50 and 25 mg/mL, with and without sodium metabisulfite preservative, in portable infusion pump cassettes (Pharmacia) stored at 4 and 23°C.<sup>1505</sup> At both concentrations with and without sodium metabisulfite at 4 and 23°C, samples remained clear and colorless.<sup>1505</sup> Morphine sulfate losses of less than 10% were found during 31 days of storage.<sup>1505</sup>

Stiles et al. studied the stability of undiluted morphine sulfate 25 and 15 mg/mL in pump reservoirs (Pharmacia Deltec) stored at 5°C in the dark and 25°C for 30 days.<sup>1507</sup> After the initial storage period, the solutions were subsequently stored at 37°C and pumped at a flow rate of 0.4 mL/hr for 3 days to simulate patient use.<sup>1507</sup> No color change or precipitation occurred in any sample.<sup>1507</sup> Little to no losses were detected; in fact, increased concentrations were observed, especially at room temperature.<sup>1507</sup> The concentration increases were attributed to water evaporation during storage.<sup>1507</sup> The authors recommended a maximum storage of 30 days under refrigeration and 14 days at room temperature because of the evaporation.<sup>1507</sup>

### Elastomeric Reservoir Pumps

Morphine sulfate 15 mg/mL and 2 mg/mL diluted with sterile water for injection was stored at 4 and 24°C in Intermate 200 (Infusion Systems) and Infusor (Baxter) disposable elastomeric infusion devices.<sup>1504</sup> In the Intermate 200 with 100 mL of morphine sulfate solution, little or no loss occurred in 15 days at either 4 or 24°C and even at 31°C (simulating use next to a patient's skin or clothing).<sup>1504</sup> In the Infusor, with 50 mL, losses of 5% or more were observed in 12 days in some containers.<sup>1504</sup>

Morphine sulfate 0.5 mg/mL in both dextrose 5% and sodium chloride 0.9% was evaluated for binding potential to natural rubber elastomeric reservoirs (Baxter). No binding was found after storage for 2 weeks at 35°C with gentle agitation.<sup>2014</sup>

Morphine sulfate 2 and 10 mg/mL is reported to be physically and chemically stable in Accufuser Plus silicone balloon infusers when stored at room temperature and refrigerated. Little or no loss of morphine sulfate occurred in 40 days.<sup>2678</sup>

### Implantable Pumps

Morphine sulfate 10 mg/mL was filled into a VIP 30 implantable infusion pump (Fresenius) and associated capillary tubing and stored at 37°C. No morphine loss and no contamination from components of pump materials occurred during 8 weeks of storage.<sup>1903</sup>

Morphine sulfate (Infumorph) 20 mg/mL with clonidine hydrochloride (Boehringer Ingelheim) 50 mcg/mL and morphine sulfate 2 mg/mL with clonidine hydrochloride 1.84 mg/mL were evaluated in SynchroMed EL (Medtronic) implantable pumps with silicone elastomer intrathecal catheters at 37°C for 3 months. No visible incompatibilities were observed; delivered concentrations of both drugs were in the range of 94 to 99.6% throughout the study. Furthermore, no impairment of mechanical performance of the pump or any of its components was found.<sup>2477</sup>

An admixture of bupivacaine hydrochloride 25 mg/mL, clonidine hydrochloride 2 mg/mL, and morphine sulfate 50 mg/mL in sterile water for injection was reported to be physically and chemically stable for 90 days at 37°C in SynchroMed implantable pumps. Little or no loss of any of the drugs was found.<sup>2585</sup>

Clonidine hydrochloride and morphine sulfate powders were dissolved in ziconotide acetate (Elan) injection to yield concentrations of 2 and 35 mg/mL and 25 mcg/mL, respectively. Stored

at 37°C, 11% ziconotide loss in 7 days, 4% clonidine loss in 20 days, and no morphine loss in 28 days occurred.<sup>2752</sup>

### Other Devices

The stability of 2 intrathecal solutions of morphine sulfate 10 mg/mL in sodium chloride 0.9% (isobaric) and 5 mg/mL in dextrose 7% in water (hyperbaric) was evaluated. The solutions were stored at 4 and 37°C in glass ampuls and pump reservoirs composed of silicone rubber reinforced with polyester (Cordis Europa). No precipitation or discoloration and no loss of morphine sulfate or increase in degradation products occurred in the solutions in glass ampuls after 2 months at either temperature. However, in the pump reservoirs, the isobaric solution in sodium chloride 0.9% developed a yellow color. Furthermore, a decomposition product, pseudomorphine, was detectable in 3 days and increased to 1% in 1 month at 37°C. This level was 20 times that of the pseudomorphine found in the hyperbaric dextrose 7% in water solution under the same conditions. The decomposition was attributed to dissolved oxygen, ethylene oxide sterilant, and silicone rubber.<sup>1508</sup>

### Central Venous Catheter

Morphine sulfate (Astra) 1 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Compatibility Information

### Solution Compatibility

TPN #71 <sup>d</sup>	<sup>a</sup>	LI	100 mg	Physically compatible and no morphine loss in 36 hr at 22°C	1000	C

<sup>a</sup> Tested in PVC containers.

<sup>b</sup> Tested in both glass and PVC containers.

<sup>c</sup> Note: Not suitable for large-volume infusion.

<sup>d</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TPN indicates a 2-in-1 admixture.

<sup>e</sup> Tested in Pharmacia or SIMS Deltec medication cassette reservoirs.

<sup>f</sup> Tested in Pharmacia Deltec PVC/Kalex phthalate ester medication cassette reservoirs.

<sup>g</sup> Tested in Pharmacia cassette reservoirs.

<sup>h</sup> Tested in Cormed III Kalex reservoirs.

<sup>i</sup> Prepared from morphine sulfate powder.

<sup>j</sup> Tested in polypropylene syringes.

<sup>k</sup> Tested in ANAPA Plus (E-WHA International) ambulatory infusion device and PEGA (Pegasus) sets.

Promethazine HCl	WY	12.5 mg	WY	8 mg	Cloudiness develops	98	I
Ranitidine HCl	GL	50 mg/2 mL	AH	10 mg/1 mL	Physically compatible for 1 hr at 25°C	978	C
Ropivacaine HCl	FRK <sup>i</sup>	7.5 mg/mL <sup>e</sup>	CDM	3.5 mg/mL <sup>e</sup>	Visually compatible and chemically stable for up to 3 day at 5°C	3493	C
Ropivacaine HCl	FRK <sup>i</sup>	7.5 mg/mL <sup>e</sup>	CDM	3.5 mg/mL <sup>e</sup>	Chemically unstable after 6 hr at 21 and 31°C	3493	I
Salbutamol sulfate	GL	2.5 mg/2.5 mL <sup>f</sup>	AB	5 mg/0.5 mL	Physically compatible for 1 hr	1904	C
Scopolamine HBr		0.6 mg/1.5 mL	WY	15 mg/1 mL	Physically compatible for at least 15 min	14	C
Scopolamine HBr	ST	0.4 mg/1 mL	ST	15 mg/1 mL	Physically compatible for at least 15 min	326	C
Scopolamine HBr	BP	5 mg/5 mL	BP	500 mg/5 mL	Little scopolamine loss in 14 days at room temperature or 37°C. Morphine not tested	1609	C
Ziconotide acetate	ELN	25 mcg/mL	BB	35 mg/mL <sup>h</sup>	No loss of either drug in 17 days at 5°C	2702	C
Ziconotide acetate	EI <sup>j</sup>	1 mcg/mL <sup>e</sup>	CDM	3.5 mg/mL <sup>e</sup>	Visually compatible and chemically stable for up to 3 days at 5°C	3493	C
Ziconotide acetate	EI <sup>j</sup>	1 mcg/mL <sup>e</sup>	CDM	3.5 mg/mL <sup>e</sup>	Chemically unstable after 6 hr at 21 and 31°C	3493	I

<sup>a</sup> Tested in sterile water for injection.

<sup>b</sup> Test performed using the formulation WITHOUT edetate disodium.

<sup>c</sup> Morphine sulfate powder dissolved in dextrose 5%.

<sup>d</sup> Morphine sulfate powder dissolved in water and sodium chloride 0.9%.

<sup>e</sup> Tested in sodium chloride 0.9%.

<sup>f</sup> Both preserved (benzyl alcohol 0.9%; benzalkonium chloride 0.01%) and unpreserved sodium chloride 0.9% were used as a diluent.

<sup>g</sup> Extemporaneously compounded from bulk drug powders.

<sup>h</sup> Morphine sulfate powder dissolved in ziconotide acetate injection.

<sup>i</sup> Tested with ziconotide acetate (EI) 1 mcg/mL.

<sup>j</sup> Tested with ropivacaine HCl (FRK) 7.5 mg/mL.

**Y-Site Injection Compatibility (1:1 Mixture)****Morphine sulfate**

<sup>w</sup> Salt not specified.

<sup>x</sup> Test performed using the formulation WITH edetate disodium.

**Additional Compatibility Information****Bupivacaine**

Bupivacaine hydrochloride 25 mg/mL admixed with morphine sulfate 50 mg/mL in sterile water for injection appeared to prevent the formation of precipitation that occurs with morphine sulfate 50 mg/mL alone when refrigerated.<sup>2378</sup>

Bupivacaine hydrochloride 2.5 mg/mL admixed with morphine sulfate 5 mg/mL in sodium chloride 0.9% and bupivacaine hydrochloride 25 mg/mL admixed with morphine sulfate 50 mg/mL in sterile water for injection exhibited little or no loss of either drug in 60 days at 4 and 23°C. The slight yellow discoloration that appeared in the high concentration samples was not indicative of drug decomposition. Samples stored for 2 days at 37°C and frozen for 2 days at -20°C resulted in little or no

loss of either drug. However, the frozen samples upon thawing exhibited the formation of large amounts of microparticulates numbering in the thousands per mL, possibly shed by the syringe components.<sup>2378</sup>

**Clonidine Hydrochloride**

Clonidine hydrochloride (Fujisawa) 100 mcg/mL and morphine sulfate (Elkins-Sinn) 10 mg/mL were mixed in equal quantities, transferred to flint glass vials with rubber stoppers, and stored for 14 days at controlled room temperature protected from light. The solutions remained clear and colorless with no increase in particulate content. Little or no change in the concentration of either drug occurred.<sup>2069</sup>

Clonidine hydrochloride 0.25 mg/mL admixed with morphine sulfate 5 mg/mL in sodium chloride 0.9% and clonidine

hydrochloride 4 mg/mL admixed with morphine sulfate 50 mg/mL in sterile water for injection exhibited little or no loss of either drug at 4 and 23°C. The slight yellow discoloration that appeared in the high concentration samples was not indicative of drug decomposition. Samples stored for 2 days at 37°C and frozen for 2 days at -20°C resulted in little or no loss of either drug. However, a precipitate formed in the frozen samples as

freezing occurred and in the refrigerated high concentration samples after 2 to 4 days. Upon warming to room temperature the precipitate redissolved, but the samples exhibited large amounts of undissolved microparticulates numbering in the thousands per mL remaining in the solutions, possibly shed by the syringe components.<sup>2380</sup>

## Moxifloxacin Hydrochloride

AHFS 8:12.18

### Products

Moxifloxacin hydrochloride (Avelox, Merck) is available as a single-use (preservative-free), premixed, ready-to-use solution of moxifloxacin 400 mg in 250 mL of sodium chloride 0.8% in a flexible container.<sup>3175</sup> Hydrochloric acid and/or sodium hydroxide may have been added to adjust the pH.<sup>3175</sup> No further dilution of the solution is necessary.<sup>3175</sup>

Moxifloxacin hydrochloride (Fresenius Kabi) also is available as a single-use, premixed, ready-to-use solution of moxifloxacin 400 mg in a flexible plastic (Freeflex) container.<sup>3176</sup> Each 250-mL bag also contains sodium acetate trihydrate 1702.5 mg and disodium sulfate 2840 mg in water for injection.<sup>3176</sup> Sulfuric acid may have been added to adjust the pH.<sup>3176</sup>

### Equivalency

Moxifloxacin hydrochloride 437.5 mg is equivalent to moxifloxacin 400 mg.<sup>3176</sup>

### pH

The pH of moxifloxacin hydrochloride (Avelox) solution is from 4.1 to 4.6.<sup>3175</sup> The pH of moxifloxacin hydrochloride (Fresenius Kabi) solution is from 5 to 6.<sup>3176</sup>

### Sodium Content

Each 250 mL of moxifloxacin hydrochloride (Avelox, Merck) solution contains approximately 34.2 mEq (787 mg) of sodium.<sup>3175</sup>

Each 250 mL of moxifloxacin hydrochloride (Fresenius Kabi) solution contains approximately 52.5 mEq (1207 mg) of sodium.<sup>3176</sup>

### Trade Name(s)

Avelox

### Administration

Moxifloxacin hydrochloride is administered intravenously by slow infusion over 60 minutes.<sup>3175 3176</sup> The solution may be infused directly or through a Y-type infusion set.<sup>3175 3176</sup> The solution must *not* be infused rapidly or as a bolus; it also is not intended for intra-arterial, intramuscular, intrathecal, intraperitoneal, or subcutaneous administration.<sup>3175 3176</sup>

Moxifloxacin hydrochloride should not be infused simultaneously through a line being used to administer other drugs.<sup>3175 3176</sup> If a common intravenous line is being used to administer other drugs in addition to moxifloxacin hydrochloride, the infusion line should be flushed prior to and following infusion of moxifloxacin hydrochloride solution with a compatible infusion solution.<sup>3175 3176</sup>

### Stability

Moxifloxacin hydrochloride injection is a clear yellow solution.<sup>3175 3176</sup> One manufacturer notes that this yellow color is not affected by nor indicative of the stability of the product.<sup>3175</sup>

Intact containers of moxifloxacin hydrochloride should be stored at controlled room temperature.<sup>3175 3176</sup> The solution should not be refrigerated because precipitation may result.<sup>3175 3176</sup> Because of light sensitivity, moxifloxacin hydrochloride (Fresenius Kabi) solution should be stored in its overwrap until immediately prior to use.<sup>3176</sup>

Moxifloxacin hydrochloride solution should be visually inspected for particulate matter and discoloration prior to administration; if particulate matter is present or discoloration occurs, the solution should not be used.<sup>3175 3176</sup> Any unused portion of the solution should be discarded.<sup>3175 3176</sup>

## Additional Compatibility Information

### Peritoneal Dialysis Solutions

Moxifloxacin hydrochloride 25 mg/mL in 2 peritoneal dialysis solutions was evaluated for stability. No color change or precipitation occurred. In Dianeal PD1 1.36% and 3.86%, moxifloxacin

hydrochloride lost 2% and 9%, respectively, in 14 days at 4°C, and 3% and 11%, respectively, in 7 days at 25°C. Losses at 37°C were higher. In Dianeal PD1 1.36%, 10% loss occurred in 3 days; in Dianeal PD1 3.86%, 7% loss occurred in 12 hours and 13% loss occurred in 24 hours.<sup>2712</sup>

Selected Revisions January 31, 2020. © Copyright, October 2010. American Society of Health-System Pharmacists, Inc.

## Multivitamins

### AHFS 88:28

#### Products

Multivitamin products for parenteral administration are available in a variety of compositions and sizes. The following products are representative formulations.

M.V.I. Adult is available as a package of 2 vials (labeled Vial 1 and Vial 2) that are prepared for use by transferring the contents of Vial 1 into Vial 2 and mixing gently. After mixing, the product contains:<sup>1(5/07)</sup>

Ascorbic acid	200 mg
Vitamin A (retinol)	1 mg
Vitamin D (ergocalciferol)	5 mcg
Thiamine (as hydrochloride)	6 mg
Riboflavin (as 5'-phosphate sodium)	3.6 mg
Pyridoxine hydrochloride	6 mg
Niacinamide	40 mg
Dexpanthenol	15 mg
Vitamin E ( <i>dl</i> - $\alpha$ tocopheryl acetate)	10 mg
Vitamin K	150 mcg
Folic acid	600 mcg
Biotin	60 mcg
Vitamin B <sub>12</sub> (cyanocobalamin)	5 mcg

The product also contains propylene glycol 30%, polysorbate 80 1.4%, citric acid, and sodium hydroxide and/or hydrochloric acid in water for injection. The concentrated vitamins must be diluted for use; do not give undiluted.<sup>1(5/07)</sup>

M.V.I.-12 has the same vitamin content as M.V.I. Adult except for the absence of vitamin K.<sup>1(5/07)</sup>

M.V.I. Pediatric is available as a lyophilized powder in vials containing a single dose. Each single dose contains:<sup>1(5/07)</sup>

Ascorbic acid	80 mg
Vitamin A (retinol)	0.7 mg
Vitamin D (ergocalciferol)	10 mcg
Thiamine (as hydrochloride)	1.2 mg
Riboflavin (as 5'-phosphate sodium)	1.4 mg
Pyridoxine (as hydrochloride)	1 mg
Niacinamide	17 mg
Dexpanthenol	5 mg

Vitamin E ( <i>dl</i> - $\alpha$ tocopheryl acetate)	7 mg
Biotin	20 mcg
Folic acid	140 mcg
Cyanocobalamin	1 mcg
Phytonadione	200 mcg

M.V.I. Pediatric also contains, in each vial, mannitol 375 mg, polysorbate 80 50 mg, polysorbate 20 0.8 mg, butylated hydroxytoluene 58 mcg, butylated hydroxyanisole 14 mcg, and sodium hydroxide for pH adjustment.<sup>1(5/07)</sup>

Reconstitute the single-dose vial with 5 mL of sterile water for injection, dextrose 5%, or sodium chloride 0.9% and swirl gently. The solution is ready within 3 minutes. This solution must be further diluted for use; do not give it undiluted.<sup>1(5/07)</sup>

#### Administration

Multivitamin infusion preparations are administered by intravenous infusion only. They should not be given by direct intravenous injection. M.V.I. Adult is diluted in not less than 500 mL but preferably 1000 mL of intravenous infusion solution for administration. M.V.I. Pediatric should be added to at least 100 mL of a compatible intravenous infusion solution for administration.<sup>1(5/07)</sup>

#### Stability

Multivitamin products for infusion should be stored under refrigeration and protected from light. Since some of the vitamins, especially A, D, and riboflavin, are light sensitive, light protection is necessary. After reconstitution of M.V.I. Pediatric, use of the product without delay is recommended. However, if this is not possible, the manufacturer permits use within a maximum of 4 hours from the initial penetration of the closure.<sup>1(5/07)</sup>

#### Light Effects

The effects of photoirradiation on a FreAmine II-dextrose 10% parenteral nutrition solution containing 1 mL/500 mL of multivitamins (USV) were evaluated. During simulated continuous administration to an infant at 0.156 mL/min, the amino acids were stable when the bottle, infusion tubing, and collection bottle were shielded with foil. Only 20 cm of tubing in the incubator was exposed to light. However, if the flow was stopped, marked reductions in methionine (40%), tryptophan (44%), and histidine (22%) occurred in the solution exposed to light for 24 hours. In a similar solution without vitamins, only the tryptophan concentration decreased. The difference was attributed to the presence of riboflavin, a photosensitizer. The authors recommended administering the multivitamins separately and shielding from light.<sup>833</sup>

The stability of 5 B vitamins was studied over 8 hours in representative parenteral nutrition solutions exposed to fluorescent light, indirect sunlight, or direct sunlight. One 5-mL vial of multivitamin concentrate (Lyphomed) and 1 mg of folic acid (Lederle) were added to a liter of parenteral nutrition solution composed of amino acids 4.25% and dextrose 25% (Travenol) with standard electrolytes and trace elements. The 5 B vitamins were stable for 8 hours at room temperature when exposed to fluorescent light. In addition, folic acid and niacinamide were stable over 8 hours in direct or indirect sunlight. Exposure to indirect sunlight appeared to have little or no effect on thiamine hydrochloride and pyridoxine hydrochloride in 8 hours, but riboflavin-5'-phosphate lost 47%. Direct sunlight caused a 26% loss of thiamine hydrochloride and an 86% loss of pyridoxine hydrochloride in 8 hours. A 4-hour exposure of riboflavin-5'-phosphate to direct sunlight resulted in a 98% loss.<sup>842</sup>

A parenteral nutrition solution in glass bottles exposed to sunlight was studied. Vitamin A decomposed rapidly, losing more than 50% in 3 hours. The decomposition could be slowed by covering the bottle with a light-resistant vinyl bag, resulting in about a 25% loss in 3 hours. Vitamin E was stable in the parenteral nutrition solution in glass bottles exposed to sunlight, with no loss occurring during 6 hours of exposure.<sup>1040</sup>

Vitamin A rapidly and significantly decomposes when exposed to daylight. The extent and rate of loss were dependent on the degree of exposure to daylight which, in turn, depended on various factors such as the direction of the radiation, time of day, and climatic conditions. Delivery of less than 10% of the expected amount was reported.<sup>1047</sup> In controlled light experiments, the decomposition initially progressed exponentially. Subsequently, the rate of decomposition slowed. This result was attributed to a protective effect of the degradation products on the remaining vitamin A. The presence of amino acids provided greater protection. Compared to degradation rates in dextrose 5%, decomposition was reduced by up to 50% in some amino acid mixtures.<sup>1048</sup>

The stability of several water-soluble vitamins in dextrose 5% and sodium chloride 0.9% in polyvinyl chloride (PVC) and Clear-Flex containers was evaluated. Thiamine, riboflavin, ascorbic acid, and folic acid were stable at 23°C when protected from light, exhibiting 10% or less loss in 24 hours. When exposed to light, thiamine and folic acid were stable but ascorbic acid was reduced by approximately 50 to 65% and riboflavin was completely lost.<sup>1509</sup>

The stability of phytonadione in a TPN solution containing amino acids 2%, dextrose 12.5%, "standard" electrolytes, and M.V.I. Pediatric over 24 hours while exposed to light was evaluated. Vitamin loss was about 7% in 4 hours and 27% in 24 hours. Some loss was attributed to the light sensitivity of the phytonadione.<sup>1815</sup>

Substantial loss of retinol all-*trans* palmitate and phytonadione was reported from both TPN and TNA admixtures due to exposure to sunlight. In 3 hours of exposure to sunlight, essentially total loss of retinol and 50% loss of phytonadione had occurred. The presence or absence of lipids did not affect stability. In contrast, tocopherol concentrations remained

essentially unchanged by exposure to sunlight through 12 hours. The container material used to store the nutrition admixtures affected the concentration of the vitamins as well. Losses were greatest (10 to 25%) in PVC containers and were slightly better in EVA and glass containers.<sup>2049</sup>

### Sorption

The following vitamins did not reveal significant sorption to a PVC plastic test strip in 24 hours:<sup>12</sup>

- Ascorbic acid
- Niacinamide
- Pyridoxine hydrochloride
- Riboflavin
- Thiamine hydrochloride
- Vitamin D
- Vitamin E acetate

Riboflavin was shown not to exhibit sorption to PVC bags and tubing, polyethylene tubing, Silastic tubing, and polypropylene syringes.<sup>536 606</sup>

Vitamin A (as the acetate) (Sigma) 7.5 mg/L displayed 66.7% sorption to a PVC plastic test strip in 24 hours. The presence of dextrose 5% and sodium chloride 0.9% increased the extent of the sorption.<sup>12</sup>

In another report, vitamin A acetate 3 mg/L displayed 78% sorption to 200-mL PVC containers after 24 hours at 25°C with gentle shaking. The sorption was increased by 10% in sodium chloride 0.9% and by 20% in dextrose 5%.<sup>133</sup>

However, vitamin A delivery is also reduced in glass intravenous containers. At a concentration of 10,000 units/L in glass and PVC plastic containers protected from light with aluminum foil, 77 and 71%, respectively, of the vitamin A were delivered over a 10-hour period. Without light protection, 61% was delivered from glass and 49% from PVC plastic containers over a 10-hour period.<sup>290</sup>

In another test using multivitamin infusion (USV), 1 ampul per liter of sodium chloride 0.9% in glass and PVC plastic containers not protected from light, 69.4 and 67.9% of the vitamin A were delivered from glass and PVC containers, respectively, over a 10-hour period. The amount of vitamin A was constant over the test period.<sup>282</sup>

The delivery of vitamins A, D, and E from a parenteral nutrition solution composed of 3% amino acid solution (Pharmacia) in dextrose 10% with electrolytes, trace elements, vitamin K, folate, and vitamin B<sub>12</sub> was evaluated. To this solution was added 6 mL of multivitamin infusion (USV). The solution was prepared in PVC bags (Travenol), and administration was simulated through a fluid chamber (Buretrol) and infusion tubing with a 0.5- $\mu$ m filter at 10 mL/hr. During the first 60 to 90 minutes, minimal delivery of the vitamins occurred. This was followed by a rise and plateau in the delivered vitamins, which were attributed to an increasing saturation of adsorptive binding sites in the tubing. The total amounts delivered over 24 hours were 31% for vitamin A, 68% for vitamin D, and 64% for vitamin E. Sorption of the vitamins was found in the PVC bag, fluid chamber, and tubing. Decomposition was not a factor.<sup>836</sup>

A patient receiving 3000 international units of retinol daily in a parenteral nutrition solution experienced 2 episodes of night blindness. The pharmacy prepared the parenteral nutrition solution in 1-L PVC bags in weekly batches and stored them at 4°C in the dark until use. A subsequent *in vitro* study showed losses of vitamin A of 23 and 77% in 3- and 14-day periods, respectively, under these conditions. About 30% of the lost vitamin A could be extracted from the PVC bag.<sup>1038</sup>

Vitamin A was lost from multivitamin infusion (USV) in a neonatal parenteral nutrition solution. The solution was prepared in colorless glass bottles and run through an administration set with a burette (Travenol). The total loss of vitamin A was 75% in 24 hours, with about 16% as decomposition in the glass bottle. The decomposition was not noticeable during the first 12 hours, but then vitamin A levels fell rather precipitously to about one-third of the initial amount. The balance of the loss, averaging about 59%, occurred during transit through the administration set. Removal of the inline filter and treatment of the set with albumin human had no effect on vitamin A delivery. Increasing three- to fourfold the amount of vitamin A was suggested to compensate for the losses.<sup>1039</sup>

A 50% loss of vitamin A from a bottle of parenteral nutrition solution prepared with multivitamin infusion (USV) after 5.5 hours of infusion was noted. The amount delivered through an Ivex-2 filter set was only 6.3% of the added amount. Similar quantities were found after 20 hours of infusion. Vitamin A binding to the infusion bottles and tubing was confirmed.<sup>704</sup>

Solutions containing multivitamin infusion (USV) spiked with <sup>3</sup>H-labeled retinol in intravenous tubing protected from light and agitated to simulate flow for 5 hours were evaluated. About half of the vitamin A was lost in 30 minutes, and 88 to 96% was lost in 5 hours.<sup>1049</sup>

The stability of vitamin E (alpha-tocopherol acetate from M.V.I.-1000 or Soluzyme) and selenium (from Selepen) in amino acids (Abbott) and dextrose in PVC bags was studied. Exposure to fluorescent light and room temperature (23°C) for 24 hours and simulated infusion at 50 mL/hr for 8 hours through a Medlon TPN administration set with a 0.22- $\mu$ m filter did not affect the concentrations of vitamin E and selenium.<sup>1224</sup>

The stability of numerous vitamins in parenteral nutrition solutions composed of amino acids (Kabi-Vitrum), dextrose 30%, and fat emulsion 20% (Kabi-Vitrum) in a 2:1:1 ratio with electrolytes, trace elements, and both fat- and water-soluble vitamins was reported. The admixtures were stored in darkness

at 2 to 8°C for 96 hours with no significant loss of retinyl palmitate, alpha-tocopherol, thiamine mononitrate, sodium riboflavin-5'-phosphate, pyridoxine hydrochloride, nicotinamide, folic acid, biotin, sodium pantothenate, and cyanocobalamin. Sodium ascorbate and its biologically active degradation product, dehydroascorbic acid, totaled 59 and 42% of the nominal starting concentration at 24 and 96 hours, respectively.<sup>1225</sup>

When the admixture was subjected to simulated infusion over 24 hours at 20°C, either exposed to room light or light protected, or stored for 6 days in the dark under refrigeration and then subjected to the same simulated infusion, once again the retinyl palmitate, alpha-tocopherol, and sodium riboflavin-5'-phosphate did not undergo significant loss. However, sodium ascorbate and its degradation product, dehydroascorbic acid, had initial combined concentrations of 51 to 65% of the nominal initial concentration, with further declines during infusion. Light protection did not significantly alter the loss of total ascorbic acid.<sup>1225</sup>

Neonatal parenteral nutrition solutions containing multivitamin infusion prepared in bags were delivered at 10 mL/hr through Buretrol sets (Travenol). The bags and sets were protected from light. About 26% of the vitamin A was lost before the flow was started. At 10 mL/hr, about 67% was lost from the effluent. More rapid flow reduced the extent of loss. Analysis of clinical samples of parenteral nutrition solutions showed losses of 21 to 57% after 20 hours. Because losses after 5 hours were of the same magnitude, it was concluded that the loss occurs rapidly and is not due to decomposition.<sup>1049</sup>

Retinol losses of 40% occurred in 2 hours and 60% in 5 hours from parenteral nutrition solutions pumped at 10 mL/hr through standard infusion sets at room temperature. The retinol concentration in the bottle remained constant while the retinol in the effluent decreased. Antioxidants had no effect. Much of the vitamin A was recoverable from the tubing.<sup>1050</sup>

To minimize the importance of this sorption, Allwood suggested using vitamin A palmitate instead of acetate; he stated that vitamin A palmitate does not sorb to PVC. However, this does not alter the problem of degradation from exposure to light.<sup>1033</sup>

### Plasticizer Leaching

Multivitamins (Lyphomed) 1 mL in 50 mL of dextrose 5% leached insignificant amounts of diethylhexyl phthalate (DEHP) plasticizer due to the surfactant polysorbate 80 in the formulation. This finding is consistent with the low surfactant concentration (0.032%) in the admixture solution.<sup>1683</sup>

## Additional Compatibility Information

### Parenteral Nutrition Solutions

In a parenteral nutrition solution composed of amino acids, dextrose, electrolytes, trace elements, and multivitamins in PVC bags stored at 4 and 25°C, vitamin A rapidly deteriorated to 10% of the initial concentration in 8 hours at 25°C when exposed to light. The decomposition was slowed by light protection and refrigeration, with a loss of about 25% in 4 days. Folic acid concentration dropped 40% initially on admixture and then remained relatively constant for 28 days of storage. About 35% of the ascorbic acid was lost in 39 hours at 25°C when exposed to light. The loss was reduced to a negligible amount in 4 days by refrigeration and light protection. Thiamine content dropped by 50% initially but then remained unchanged over 120 hours of storage.<sup>1063</sup>

The stability of ascorbic acid in parenteral nutrition solutions, with and without fat emulsion, was studied. Both with and without fat emulsion, the total vitamin C content (ascorbic acid plus dehydroascorbic acid) remained above 90% for 12 hours when the solutions were exposed to fluorescent light and for 24 hours when they were protected from light. When stored in a cool dark place, the solutions were stable for 7 days.<sup>1227</sup>

Samples from 24 1-L and four 2-L parenteral nutrition solutions, containing 1 vial each of multivitamin concentrate (USV), were evaluated for thiamine hydrochloride content 48 and 72 hours after mixing. The parenteral nutrition solutions contained amino acids 2.75 to 5%, dextrose 15 to 25%, and electrolytes. Thiamine hydrochloride was stable in all of the solutions tested in spite of approximately 0.05% sulfite content.<sup>843</sup>

The vitamins in Cernevit (Baxter) diluted in three 2-in-1 parenteral nutrition admixtures were tested for stability over 48 hours. Nearly all of the vitamins retained their initial

concentrations. However, ascorbic acid exhibited losses of about 5%, 13%, and 17% in TPNs with dextrose concentrations of 10, 15, and 25%, respectively.<sup>2796</sup>

### Erythromycin

Erythromycin 5 mg/mL as the lactobionate in pH 8 buffer was combined with riboflavin in concentrations varying from 1 mg/mL to 20 mcg/mL. On exposure to light for 4 hours, almost total decomposition of the erythromycin occurred, with only 4 to 12% remaining. Protection from light resulted in 12 to 25% decomposition. When no riboflavin was present, 10% or less decomposition of the erythromycin occurred. It was concluded that a photodynamic decomposition reaction was taking place.<sup>564</sup>

### Penicillin G

The times to 10% decomposition of combinations of penicillin G potassium buffered with multivitamin infusion concentrate in dextrose 5% and sodium chloride 0.9% have been calculated on the pH of the admixture:<sup>304</sup>

Penicillin G Potassium	Multivitamin Infusion Concentrate	pH	Time to 10% Decomposition
1 million units/L	1 mL/L	5.1	6.51 hr
1 million units/L	5 mL/L	4.9	4.56 hr
3 million units/L	1 mL/L	5.4	13.54 hr
3 million units/L	5 mL/L	5.0	6.38 hr
5 million units/L	1 mL/L	5.7	22.01 hr
5 million units/L	5 mL/L	5.1	6.51 hr
10 million units/L	1 mL/L	5.9	over 24 hr
10 million units/L	5 mL/L	5.4	13.54 hr

# Mycophenolate Mofetil Hydrochloride

AHFS 92:44

## Products

Mycophenolate mofetil hydrochloride is available as a lyophilized powder in vials containing 500 mg of mycophenolate mofetil along with polysorbate 80 25 mg and citric acid 5 mg.<sup>3516 3519</sup> Sodium hydroxide may have been added during manufacturing to adjust pH.<sup>3516 3519</sup>

Manufacturers recommend the use of dextrose 5% for reconstitution and dilution of the drug.<sup>3516 3519</sup> Individuals who handle or prepare mycophenolate mofetil hydrochloride solutions should use care and take precautions to avoid contact with the drug solution.<sup>3516 3519</sup> Each vial should be reconstituted with 14 mL of dextrose 5% and gently shaken to dissolve the drug.<sup>3516 3519</sup> The reconstituted solution must be further diluted with dextrose 5% to yield a solution with a final mycophenolate mofetil concentration of 6 mg/mL.<sup>3516 3519</sup> The volumes of dextrose 5% to be used for the dilution of 1- and 1.5-g doses of the reconstituted solution are 140 and 210 mL, respectively.<sup>3516 3519</sup> The solution should be inspected for particulate matter and discoloration.<sup>3516 3519</sup>

## pH

The pH of the reconstituted solution ranges from 2.4 to 4.1<sup>3516</sup> or 2.7 to 4.1.<sup>3519</sup>

## Trade Name(s)

CellCept

## Administration

Mycophenolate mofetil hydrochloride is administered by slow intravenous infusion over a minimum of 2 hours into either a

central line or peripheral vein.<sup>3516 3519</sup> The drug should *not* be administered by rapid or bolus administration.<sup>3516 3519</sup>

## Stability

Mycophenolate mofetil hydrochloride is a white to off-white lyophilized powder that forms slightly yellow solution upon reconstitution and dilution.<sup>3516 3519</sup> Intact vials of the drug should be stored at controlled room temperature<sup>3519</sup> or at 25°C with excursions permitted from 15 to 30°C.<sup>3516</sup> Dextrose 5% is the manufacturer-recommended diluent for reconstitution and dilution of mycophenolate mofetil hydrochloride; all other solutions are stated to be incompatible.<sup>3516 3519</sup> Reconstituted solutions and solution diluted for infusion also may be kept at 25°C.<sup>3516 3519</sup> Manufacturers indicate that administration of the diluted drug should begin within 4 hours after reconstitution and dilution of the drug.<sup>3516 3519</sup>

## Freezing Solutions

Mycophenolate mofetil (Hoffmann-La Roche, Accord) 1, 4, and 10 mg/mL in polypropylene bags of dextrose 5% (Grifols) was stable for 35 days when frozen at -15 to -25°C.<sup>3520</sup>

## Sorption

Mycophenolate mofetil (Hoffmann-La Roche, Accord) 1, 4, and 10 mg/mL prepared with dextrose 5% using a closed-system transfer device (CSTD) (Equashield) demonstrated negligible amounts of sorption to the CSTD.<sup>3520</sup>

## Nafcillin Sodium

AHFS 8:12.16.12

### Products

Nafcillin sodium is available in vials containing the equivalent of 1 and 2 g of nafcillin.<sup>4</sup> Reconstitute the 1-g vial with 3.4 mL and the 2-g vial with 6.6 mL of sterile water for injection, sodium chloride 0.9%, or bacteriostatic water for injection containing parabens or benzyl alcohol. The solution then contains nafcillin sodium equivalent to nafcillin 250 mg/mL with sodium citrate buffer. The final volumes of the 1- and 2-g vials are 4 and 8 mL, respectively.<sup>4</sup>

A 10-g pharmacy bulk vial is also available and is reconstituted with 93 mL of sterile water for injection or sodium chloride 0.9% to yield a 100-mg/mL solution with sodium citrate buffer 4 mg/mL.<sup>4</sup>

Nafcillin sodium is also available as frozen premixed solutions containing 1 and 2 g of nafcillin per minibag in dextrose 3.6% or 2%, respectively.<sup>1(2/07)</sup>

### pH

The pH of the reconstituted solution and frozen premixed solution is 6 to 8.5.<sup>4</sup>

### Osmolality

The osmolality of nafcillin sodium 250 mg/mL in sterile water for injection was 709 mOsm/kg by freezing-point depression and 665 mOsm/kg by vapor pressure.<sup>1071</sup>

The frozen premixed solutions have an osmolality of 300 mOsm/kg.<sup>4</sup>

The osmolality of nafcillin sodium (Wyeth) 40 mg/mL was determined to be 403 mOsm/kg in dextrose 5% and 402 mOsm/kg in sodium chloride 0.9%.<sup>1375</sup>

The osmolality of nafcillin sodium was calculated for the following dilutions<sup>1054</sup>:

Diluent	Osmolality (mOsm/kg)	
	50 mL	100 mL
<b>2 g</b>		
Dextrose 5%	399	334
Sodium chloride 0.9%	425	361
<b>3 g</b>		
Dextrose 5%	458	371
Sodium chloride 0.9%	485	398

The following maximum nafcillin sodium concentrations were recommended to achieve osmolalities suitable for peripheral infusion in fluid-restricted patients<sup>1180</sup>:

Diluent	Maximum Concentration (mg/mL)	Osmolality (mOsm/kg)
Dextrose 5%	71	491
Sodium chloride 0.9%	64	470
Sterile water for injection	128	319

### Sodium Content

Each gram of nafcillin sodium with sodium citrate buffer contains 2.9 mEq (66 mg) of sodium.<sup>4 27</sup>

### Administration

Nafcillin sodium may be administered intramuscularly by deep intragluteal injection, by direct intravenous injection, or by intermittent intravenous infusion. For direct intravenous injection, the dose should be diluted with 15 to 30 mL of sterile water for injection or sodium chloride 0.45 or 0.9% and given over five to 10 minutes into the tubing of a running intravenous infusion. Intermittent intravenous infusion in a concentration between 2 and 40 mg/mL should be administered slowly, over 30 to 60 minutes.<sup>4</sup>

### Stability

Intact containers should be stored at controlled room temperature or lower.<sup>4</sup> When reconstituted to a concentration of 250 mg/mL, nafcillin sodium is stable for three days at room temperature or seven days when refrigerated at 2 to 8°C.<sup>4 27</sup> At concentrations of 2 to 40 mg/mL, nafcillin sodium is stable for 24 hours at room temperature or 96 hours under refrigeration.<sup>4</sup>

Commercially available frozen premixed nafcillin sodium solutions, thawed at room temperature or under refrigeration, are stable for 72 hours at 25°C and 21 days at 5°C.<sup>4</sup>

The activity of nafcillin 100 mg/L was evaluated in peritoneal dialysis fluids containing dextrose 1.5 or 4.25% (Dianeal 137, Travenol). Storage at 25°C resulted in no loss of antimicrobial activity in 24 hours.<sup>515</sup>

The stability of nafcillin sodium (Wyeth) 100 mg/L in peritoneal dialysis solutions (Dianeal 137 and PD2) with heparin sodium 500 units/L was evaluated. About 98% activity remained after 24 hours at 25°C.<sup>1228</sup>

## pH Effects

The stability of nafcillin sodium is pH dependent, with a maximum stability at pH 6 and a preferred range of pH 5 to 8. Drug decomposition is increased as pH values vary from this range. Additives that may result in a final pH of above 8 or below 5 should not be mixed with nafcillin sodium.<sup>27</sup>

## Freezing Solutions

At a concentration of 250 mg/mL in sterile water for injection and frozen at  $-20^{\circ}\text{C}$ , the drug is stable for up to three months.<sup>27, 123</sup>

In one study, however, when nafcillin sodium (Wyeth) 1 g/4 mL was frozen at  $-20^{\circ}\text{C}$  in glass syringes (Hy-Pod), the drug was stable for nine months.<sup>532</sup>

In another study, nafcillin sodium (Wyeth) 1 g/50 mL of dextrose 5% in PVC bags frozen at  $-20^{\circ}\text{C}$  for 30 days and then thawed by exposure to ambient temperature or microwave radiation showed no evidence of precipitation or color change but had a 2 to 3% loss. Subsequent storage of the admixture at room temperature for 24 hours also yielded physically compatible solutions with no additional loss of activity.<sup>555</sup>

## Syringes

Nafcillin sodium (Apothecon) 10 mg/mL in sodium chloride 0.9% was packaged in 10-mL polypropylene syringes (Becton Dickinson) and stored at 5 and  $25^{\circ}\text{C}$ . The solutions remained clear under refrigeration for 44 days and at room temperature for seven days. A yellow color developed after 14 days at room temperature. About 2% loss of nafcillin sodium occurred after seven days and 18% loss in 14 days at  $25^{\circ}\text{C}$ . Under refrigeration, 1% loss occurred after 44 days. Stability in glass containers was comparable.<sup>2325</sup>

## Ambulatory Pumps

Nafcillin sodium (Marsam) 20 mg/mL in sterile water for injection in PVC portable pump reservoirs (Pharmacia Deltec) exhibited no loss in three days stored at  $25^{\circ}\text{C}$  and in 14 days at  $5^{\circ}\text{C}$ . However, at a concentration of 120 mg/mL, 6% loss was found in three days at  $25^{\circ}\text{C}$ , and 2% loss occurred in 14 days at  $5^{\circ}\text{C}$ .<sup>2080</sup>

Nafcillin sodium 40 and 50 mg/mL in sodium chloride 0.9% precipitated in as little as one day at the simulated ambulatory use temperature of  $35^{\circ}\text{C}$ . At 20 mg/mL, precipitation appeared in three days. When stored at room temperature, no precipitation appeared at any concentration in three days.<sup>2664</sup>

## Nalbuphine Hydrochloride

AHFS 28:08.12

### Products

Nalbuphine hydrochloride is available as a 10-mg/mL solution in 1-mL ampuls and 10-mL vials and as a 20-mg/mL solution in 1-mL ampuls and 10-mL vials. Each mL of solution in vials also contains sodium citrate hydrous 0.94%, citric acid anhydrous 1.26%, methyl- and propylparabens 0.2%, and hydrochloric acid to adjust pH. The 10-mg/mL solution contains sodium chloride 0.225%. The ampul formulation contains no parabens.<sup>1(6/06)</sup>

### pH

The pH is adjusted to about 3.5 to 3.7.<sup>1(6/06)</sup>

### Administration

Nalbuphine hydrochloride is administered by subcutaneous, intramuscular, or intravenous injection.<sup>1(6/06) 4</sup>

### Stability

Intact vials and ampuls should be protected from excessive light and stored at 15 to 30°C.<sup>1(6/06) 4</sup>

### Central Venous Catheter

Nalbuphine hydrochloride (Astra) 1 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

# Naloxone Hydrochloride

## AHFS 28:10

### Products

Naloxone hydrochloride is available in the following formulations:<sup>1(6/06)</sup>

Component	Preserved (mg/mL)		Paraben-Free (mg/mL)		
	1	0.4	1	0.4	0.02
Naloxone HCl	1	0.4	1	0.4	0.02
Sodium chloride	8.35	8.6	9	9	9
Methyl- and propylparabens (9:1)	2	2	0	0	0
Sizes (mL)	10	10	2	1	2

### pH

The pH is adjusted during manufacturing with hydrochloric acid to a target pH of 3 to 4<sup>1(6/06)</sup> with a range of 3 to 6.5.<sup>17</sup>

### Osmolality

The osmolality of the 0.02-mg/mL concentration was determined to be 293 mOsm/kg by freezing-point depression and 289 mOsm/kg by vapor pressure.<sup>1071</sup>

The osmolality of naloxone hydrochloride 0.4 mg/mL was determined to be 301 mOsm/kg.<sup>1233</sup>

### Trade Name(s)

Narcan

### Administration

Naloxone hydrochloride may be administered by subcutaneous, intramuscular, or intravenous injection or by continuous intravenous infusion. Solutions for continuous intravenous infusion may be prepared as 2 mg/500 mL (4 mcg/mL) of sodium chloride 0.9% or dextrose 5%.<sup>1(6/06) 4</sup>

### Stability

Naloxone hydrochloride should be stored at room temperature and protected from excessive light. Naloxone hydrochloride should not be mixed with bisulfite, sulfite, or long-chain or high molecular weight anions or any solution with an alkaline pH.<sup>1(6/06) 4</sup>

Naloxone hydrochloride under simulated summer conditions in paramedic vehicles was exposed to 26 to 38°C over 4 weeks. Analysis found no loss of the drug under these conditions.<sup>2562</sup>

### Syringes

Naloxone hydrochloride (Astra) 0.133 mg/mL in sodium chloride 0.9% packaged in polypropylene syringes (Sherwood) was physically stable and exhibited little or no loss in 24 hours stored at 4 and 23°C.<sup>2199</sup>

<sup>e</sup> Meropenem component. Meropenem in a 1:1 fixed-ratio concentration with vaborbactam.

## Neostigmine Methylsulfate

### AHFS 12:04

### Products

Neostigmine methylsulfate is available in concentrations of 0.5 and 1 mg/mL in 10-mL vials with methyl- and propylparabens 0.2%.<sup>1(6/06)</sup>

### pH

The pH is adjusted to near 5.9 with a range of 5 to 6.5.<sup>1(6/06)</sup> 17

### Administration

Neostigmine methylsulfate may be administered intramuscularly, subcutaneously, or slowly intravenously.<sup>1(6/06)</sup> 4

### Stability

Neostigmine methylsulfate in intact containers should be stored at controlled room temperature and protected from light, freezing, and temperatures of 40°C or more.<sup>1(6/06)</sup> 4

### Syringes

In 2015, reports of decreased potency of certain drugs (e.g., neostigmine methylsulfate) stored in Becton Dickinson syringes for extended periods (i.e., exceeding 24 hours) were confirmed by the manufacturer of these syringes; the cause of this change was later identified to be the inclusion of an alternate rubber

stopper in the plunger of certain product lots of syringes.<sup>3029 3036 3037 3039 3041 3042</sup> Decreased potency was not observed when the syringes were filled and used promptly.<sup>3037</sup> Use of the alternate stopper was later discontinued and use of the primary stopper in such syringes was resumed; however, Becton Dickinson states that its general-use syringes are cleared by FDA for immediate use in fluid aspiration and injection and that such syringes, regardless of the stopper material, have not been cleared by FDA for use as a closed-container system.<sup>3391</sup>

The stability of neostigmine 0.5 mg/mL repackaged in polypropylene syringes was evaluated. Little concentration change was found after 4 weeks of storage at room temperature not exposed to direct light.<sup>2164</sup>

Neostigmine methylsulfate (Elkins-Sinn) 0.167 mg/mL in sodium chloride 0.9% packaged in polypropylene syringes (Sherwood) was physically stable and exhibited no loss in 24 hours stored at 4 and 23°C.<sup>2199</sup>

Undiluted neostigmine methylsulfate (American Pharmaceutical Partners) 1 mg/mL was packaged in 6-mL polypropylene syringes (Becton Dickinson) and stored at 23°C in fluorescent light and at 4°C for 90 days. The drug remained physically stable and under 2% loss occurred.<sup>2425</sup>

## Nesiritide

AHFS 24:12.92

### Products

Nesiritide is available in 1.5-mg single-use vials containing 1.58 mg of nesiritide with mannitol 20 mg, citric acid monohydrate 2.1 mg, and sodium citrate dihydrate 2.94 mg.<sup>1(1/07)</sup>

Reconstitute nesiritide using 5 mL of solution from a 250-mL plastic intravenous infusion container of dextrose 5%, sodium chloride 0.9%, dextrose 5% in sodium chloride 0.45%, or dextrose 5% in sodium chloride 0.225%, yielding a nesiritide concentration of 0.32 mg/mL. Gently rock the vial to aid dissolution making sure all surfaces, including the stopper, are in contact with the diluent; do not shake the vial. The reconstituted solution should be clear and colorless. Add the entire contents of the vial into the 250-mL plastic infusion solution container and invert several times to yield a nesiritide infusion concentration of 6 mcg/mL.<sup>1(1/07)</sup>

### Trade Name(s)

Natrecor

### Administration

Nesiritide is administered by an initial intravenous injection drawn from the intravenous infusion solution and given over about 1 minute followed by continuous intravenous infusion. The intravenous tubing should be primed with 5 mL of the solution before connecting to the patient's access port and before administering the initial bolus dose or beginning the infusion.<sup>1(1/07)</sup>

### Stability

Intact vials should be stored below 25°C in the original carton to protect from light. Protect the vials from freezing.<sup>1(1/07)</sup>

The manufacturer states that the reconstituted nesiritide should be used within 24 hours stored between 2 and 25°C because no antimicrobial preservative is present.<sup>1(1/07)</sup>

Nesiritide is incompatible with sodium metabisulfite and other bisulfite antioxidants used in some drug formulations. The specific formulation of the product to be used should be checked to ensure that no sulfite antioxidants are present. Drugs that contain sulfite antioxidants should not be administered into the same intravenous infusion line as nesiritide. The line should be flushed between administration of the incompatible drugs and nesiritide.<sup>1(1/07) 2625</sup>

### Sorption

The official product labeling states that nesiritide may bind to heparin-coated administration catheters decreasing the delivery of nesiritide to the patient and that heparin-coated administration lines must not be used to administer nesiritide.<sup>1(1/07)</sup>

However, a study of nesiritide delivery through unprimed PVC and polyethylene tubing, a polyurethane central catheter, and a heparin-coated PVC catheter found little alteration of the delivered concentration. About 94 to 98% of the drug was delivered through these devices compared to 98% through primed PVC tubing alone.<sup>2646</sup>

## Nicardipine Hydrochloride

AHFS 24:28.08

### Products

Nicardipine hydrochloride is available as a 2.5-mg/mL concentrate for injection in 10-mL ampuls. Each mL also contains sorbitol 48 mg, citric acid monohydrate 0.525 mg, and sodium hydroxide 0.09 mg in water for injection. Additional citric acid and/or sodium hydroxide may have been added to adjust solution pH.<sup>1(1/06)</sup>

### pH

Buffered to pH 3.5.<sup>1(1/06)</sup>

### Trade Name(s)

Cardene I.V.

### Administration

Nicardipine hydrochloride concentrate for injection must be diluted for use. It is administered as a slow continuous intravenous infusion at a concentration of 0.1 mg/mL. The infusion is prepared by adding 10 mL of nicardipine hydrochloride (25 mg) to 240 mL of compatible infusion solution, making 250 mL of a 0.1-mg/mL solution. If nicardipine hydrochloride is administered

via a peripheral vein, the infusion site should be changed every 12 hours to avoid venous irritation.<sup>1(1/06) 4</sup>

### Stability

Intact ampuls of the clear, yellow solution should be stored at controlled room temperature and protected from light. Freezing does not adversely affect the product, but exposure to elevated temperatures should be avoided.<sup>1(1/06)</sup>

### Light Effects

Deliberate exposure of a 0.1-mg/mL nicardipine hydrochloride solution to daylight resulted in about 8% loss in 7 hours and 21% loss in 14 hours. Protection from light may be considered.<sup>2193</sup>

### Sorption

Nicardipine hydrochloride (Dupont Merck) 50 and 500 mg/L in a variety of infusion solutions in polyvinyl chloride (PVC) containers showed a decline in concentration due to sorption to the plastic. Losses were rapid in Ringer's injection, lactated with up to 42% lost in 24 hours. The concentrations were stable in glass containers.<sup>1380</sup>

## Nimodipine

AHFS 24:28.08

### Products

Nimodipine 0.02% (0.2 mg/mL) is available in 50-mL brown glass vials and 250-mL brown glass bottles. The product also contains ethanol 20% (w/v), polyethylene glycol 400, sodium citrate, citric acid, and water for injection.<sup>38 115</sup>

### Administration

Nimodipine is given by intravenous infusion via a central catheter;<sup>38 115</sup> use of an infusion pump has been recommended.<sup>115</sup> Intracasternal instillation has also been described.<sup>115</sup> The drug must not be added to an infusion bag or bottle. For administration, nimodipine injection is drawn into a 50-mL syringe and connected to a three-way stopcock and polyethylene tube that permits simultaneous administration of the nimodipine and a co-infusion running at a rate of 40 mL/hr. Dextrose 5%, sodium chloride 0.9%, lactated Ringer's injection, lactated Ringer's injection with magnesium, dextran 40, mannitol 10%, albumin human 5%, and hetastarch 6% in sodium chloride 0.9% have been recommended for use as the co-infusion solution.<sup>38 115</sup>

### Stability

Nimodipine injection is a clear yellow solution. Intact containers of the drug should be stored at or below 25°C. The drug is light sensitive and should be stored in the light-protective container

within the carton that is supplied with the product. Nimodipine should not be added to infusion solution bags or bottles or mixed with other drugs. The 250-mL bottles are intended for single use only and should be pierced only once. Once pierced, the bottle should be used for no longer than 25 hours regardless of whether all of the solution has been administered.<sup>38 115</sup>

### Light Effects

Nimodipine is light sensitive. The drug drawn into a syringe for administration must be protected from direct sunlight during administration but is stable for up to 10 hours exposed to diffuse daylight and artificial light. The 250-mL infusion bottle should also be protected from direct sunlight at all times. Opaque coverings for infusion pumps and tubing or black, brown, yellow, or red infusion lines can be used when needed.<sup>38 115</sup>

### Sorption

Nimodipine reacts with PVC equipment but is compatible with polyethylene and polypropylene containers, syringes, and administration sets as well as glass containers.<sup>38 115</sup>

Nimodipine (Bayer) 0.01 mg/mL in dextrose 5% and sodium chloride 0.9% packaged in PVC, polyethylene, and glass containers exhibited only 3 to 5% loss in glass and polyethylene containers but 94% loss due to sorption in PVC containers when stored at 4 and 22°C for 24 hours protected from light.<sup>2289</sup>

## Nitroglycerin

AHFS 24:12.08

### Products

Nitroglycerin injection is available in a 5-mg/mL concentration in 5- and 10-mL vials. The product also contains ethanol 30% and propylene glycol 30% in water for injection. The pH may have been adjusted during manufacture with sodium hydroxide and/or hydrochloric acid. Nitroglycerin injection must be diluted before use.<sup>1(10/06) 4</sup>

Nitroglycerin is available premixed in dextrose 5% at concentrations of 100, 200, and 400 mcg/mL in 250- and 500-mL containers. The Baxter premixed infusions contain propylene glycol and ethanol with citric acid as a buffer and sodium hydroxide and/or hydrochloric acid, if necessary, to adjust the pH during manufacturing. The Hospira premixed infusions also contain propylene glycol (but no ethanol) and nitric acid to adjust pH during manufacturing.<sup>1(10/06)</sup>

### pH

The concentrate for injection has a pH of 3 to 6.5.<sup>1(10/06) 4</sup> The Baxter premixed infusion solution has a pH of 4 (range 3 to 5). The Hospira premixed infusion solution also has a pH of about 4 but with a range of 3 to 6.5.<sup>1(10/06)</sup>

### Osmolarity

The osmolarities of the nitroglycerin premixed infusion solutions in dextrose 5% vary by manufacturer but are all within the normal range for infusions:<sup>1(10/06)</sup>

Nitroglycerin Concentration	Osmolarity (mOsm/L)	
	Hospira	Baxter
100 mcg/mL	265	428
200 mcg/mL	277	440
400 mcg/mL	301	465

### Administration

Nitroglycerin injection is administered by intravenous infusion after dilution in dextrose 5% or sodium chloride 0.9% contained in glass bottles, using an infusion control device. The use of filters should be avoided. Various concentrations and administration rates are utilized, depending on the fluid requirements of the patient and the duration of therapy. An initial concentration of 50 to 100 mcg/mL, with adjustment to the concentration if necessary, has been recommended. The concentration should not exceed 400 mcg/mL.<sup>1(10/06) 4</sup>

Because of nitroglycerin sorption into polyvinyl chloride (PVC) plastic, dosing is higher with standard PVC administration sets and should be reduced when nonabsorbing administration sets are used.<sup>4</sup>

Inaccurate nitroglycerin dosing may occur with nonabsorbing high-density polyethylene plastic administration sets. Such tubing is less pliable than PVC and may not work well with some infusion control devices designed for PVC tubing, resulting in overinfusion.<sup>729 730 731 1120</sup>

### Stability

Nitroglycerin injections are practically colorless and stable in the intact containers. The solutions are not explosive. Storage should be at controlled room temperature; the containers should be protected from freezing.<sup>1(10/06) 4</sup> Exposure to light, even high intensity light, does not adversely affect nitroglycerin stability.<sup>506 510 928 930 1941</sup>

### pH Effects

The rate of nitroglycerin hydrolysis becomes significant at low pH values and is also quite rapid in alkaline solutions.<sup>933</sup> In neutral to weakly acidic solutions, the drug is stable. No loss was observed over 136 days at room temperature at pH 3 to 5.<sup>1072</sup>

### Syringes

Plastic syringes having polypropylene barrels and polyethylene plungers (Pharma-Plast) and all-glass containers were compared in an investigation of the possible sorption of nitroglycerin. After 24 hours of storage of aqueous nitroglycerin solutions (concentrations unspecified), no drug loss was found in either the plastic syringes or glass containers. The authors indicated that these plastic syringes could be substituted for glass syringes for use with syringe pumps.<sup>782</sup>

Nitroglycerin (DuPont) (concentration unspecified) was filled into 3-mL plastic syringes (Becton Dickinson, Sherwood Monoject, and Terumo) and stored at -20, 4, and 25°C in the dark. Nitroglycerin losses in 1 day ranged from 10 to 15% at 25°C, to 2 to 3% at 4°C, to 2% or less at -20°C. Long-term storage for 7 days at 4°C and 30 days at -20°C resulted in losses of 5 to 7% and 2% or less, respectively. The losses were presumably due to sorption to surfaces and/or the elastomeric plunger.<sup>1562</sup>

Nitroglycerin (DuPont) 50 mg/50 mL in dextrose 5% exhibited no change in appearance and about a 3.6% loss when stored in 60-mL plastic syringes (Becton Dickinson) for 24 hours at 25°C.<sup>1579</sup>

Nitroglycerin concentrate 5 mg/mL from 4 manufacturers (Abbott, DuPont, Goldline, Marion) was filled as 10 mL in 10-mL glass syringes (Becton Dickinson) and in 10-mL (Becton Dickinson) and 12-mL (Monoject) polypropylene plastic syringes. No loss of nitroglycerin content occurred in 23 hours when stored at 25°C protected from light. Mean nitroglycerin concentrations were greater than 99% and were the same for both the glass and plastic syringes.<sup>2055</sup>

Nitroglycerin 110 mcg/mL prepared from nitroglycerin 100 mcg/mL in dextrose 5% injection (Hospira) and nitroglycerin 5 mg/mL

injection (American Regent) and packaged as 10.1 mL in 12-mL polypropylene syringes (Terumo) was tested for stability at a controlled room temperature of 23 to 27°C protected from light.<sup>2976</sup> The solution exhibited no change in appearance and about an 8% loss at 14 days; calculated time to 10% loss was 24 days.<sup>2976</sup>

### Sorption

Nitroglycerin readily undergoes sorption to many soft plastics, especially PVC which is commonly used to make infusion solution bags and intravenous tubing.

Plastics such as polyethylene and polypropylene generally do not absorb nitroglycerin. Consequently, it is recommended that only infusion solution containers made from glass or a plastic known to be compatible with nitroglycerin (i.e., polyolefin) be used for mixing infusions.

To circumvent the significant loss to PVC tubing, use of the special high-density polyethylene administration sets provided by the various nitroglycerin injection manufacturers is recommended. Nitroglycerin is not significantly sorbed to these special sets, but the rate of loss to conventional PVC sets is significant (40 to 80%), although not constant nor self-limiting. Many factors including flow rate, concentration, and length of the set affect the extent of sorption. The greatest amount of sorption occurs early in the infusion. A slow rate of flow and long tubing length increase the loss. Simple calculations or corrections cannot be applied to this complex phenomenon to determine or control the actual amount of nitroglycerin delivered through PVC tubing.<sup>1(10/06) 4 503 506 508 509 510 511 721 723 724 725 726 727 728 769 770 797 930 931 932 934 943 1027 1121 1122 1392 1510 1511 1512 1796 2143 2289 2660 2792</sup>

In addition to PVC bags and infusion tubing, nitroglycerin has been demonstrated to undergo similar sorption to cellulose propionate drip chambers,<sup>725 931 1027 1512</sup> polystyrolbutadiene burettes,<sup>1512</sup> PVC pulmonary artery catheters<sup>937</sup> and central venous pressure catheters (Intracath, Deseret),<sup>938</sup> a polyurethane sponge used to defoam blood in a bubble oxygenator,<sup>939</sup> a silicone rubber membrane in a membrane oxygenator,<sup>940</sup> an infusion pump cassette (Accuset C-924, IMED),<sup>941</sup> and silicone rubber microbore intravenous infusion tubing.<sup>942</sup>

However, the clinical importance of the sorption to PVC has been questioned because nitroglycerin administration is titrated

to clinical response, not in a fixed dosage.<sup>1120 1123 2015 2016 2054</sup> A 25 to 35% loss to PVC tubing was reported at rates of nitroglycerin administration of 80 and 60 mcg/min, respectively. Polyethylene tubing delivered essentially 100% of the nitroglycerin. Nevertheless, there was no statistically significant difference in physiologic response in patients when a variety of parameters were evaluated. The type of tubing used does not influence the ultimate hemodynamic responses significantly, because even the PVC delivered a significant amount of the drug. It was advised that physiologic endpoints be monitored in patients on intravenous nitroglycerin.<sup>1120</sup>

A number of similar results were also reported.<sup>2015 2016 2054</sup> Adequate clinical response was achieved using PVC containers and tubing. However, changes in patient hemodynamic status could occur if containers for nitroglycerin infusions were changed during the treatment course; switching from PVC to glass or vice versa could require substantial adjustment in the rate of administration to achieve a similar clinical response.<sup>2016</sup>

### Filtration

Some filters absorb nitroglycerin and should be avoided.<sup>4</sup> Filtration of 250 mL of a 485-mcg/mL aqueous solution through 3 different 142-mm, 0.2- $\mu$ m filters was performed. A loss of 55% resulted with the Gelman GA filter composed of cellulose triacetate. Losses of only 5% occurred with a Millipore GS filter (a mixture of cellulose acetate and cellulose nitrate), and 2% losses occurred with a Gelman Tuffryn filter (a high-temperature aromatic polymer).<sup>724</sup>

In one study, a filter material specially treated with a proprietary agent was evaluated for a possible reduction in nitroglycerin binding. Nitroglycerin (Abbott) 62.5 mg/250 mL in dextrose 5% and in sodium chloride 0.9% was run through an administration set with a treated 0.22- $\mu$ m cellulose ester inline filter at a rate of 3 mL/min. Cumulative nitroglycerin losses of less than 6% occurred from 200 mL of either solution. However, equilibrium binding studies showed no significant differences in drug affinity between treated and untreated filter material in either solution.<sup>904</sup> Ivex integral filter and extension sets use the treated filter material.<sup>1074</sup>

## Norepinephrine Bitartrate

AHFS 12:12.12

### Noradrenaline Acid Tartrate

#### Products

Norepinephrine bitartrate is available as 1 mg/mL of norepinephrine base in 4-mL vials. Each mL of solution also contains sodium metabisulfite 0.2 mg and sodium chloride for isotonicity in water for injection.<sup>1(6/07)</sup>

#### pH

From 3 to 4.5.<sup>1(6/07)</sup>

#### Tonicity

Norepinephrine bitartrate injection is adjusted to isotonicity with sodium chloride.<sup>1(6/07)</sup>

#### Trade Name(s)

Levophed

#### Administration

Norepinephrine bitartrate is administered by intravenous infusion into a large vein, using a pump or other flow rate control device. Extravasation may cause tissue damage and should be avoided. A 4-mcg/mL dilution of norepinephrine base for infusion is usually prepared by adding 4 mg of base (4 mL) to 1000 mL of dextrose 5% with or without sodium chloride. The concentration and infusion rate depend on the patient's requirements.<sup>1(6/07)</sup>

#### Stability

Norepinephrine bitartrate in intact containers should be stored at controlled room temperature and protected from light.<sup>1(6/07)</sup> Dextrose 5% and dextrose 5% in sodium chloride 0.9% are the recommended diluents for infusion because their dextrose content provides protection against significant drug loss due to oxidation. The drug gradually darkens upon exposure to light or air and must not be used if it is discolored or has a precipitate.<sup>4</sup>

#### pH Effects

Norepinephrine bitartrate is stable at pH 3.6 to 6 in dextrose 5%.<sup>48</sup> The pH of a solution is the primary determinant of catecholamine stability in intravenous admixtures.<sup>527</sup> At a concentration of 5 mg/L in dextrose 5% at pH 6.5, norepinephrine bitartrate loses 5% in 6 hours; at pH 7.5, it loses 5% in 4 hours.<sup>77</sup> The rate of loss also increases with exposure to increasing temperatures.<sup>1929</sup>

#### Compatibility Information

##### Solution Compatibility

##### Norepinephrine bitartrate

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Amino acids 4.25%, dextrose 25%	MG	WI	4 mg	No increase in particulate matter in 24 hr at 5°C	349	C
Dextrose 5% in sodium chloride 0.9%		WI	8 mg	Physically compatible	74	C

Caution should be employed in mixing additives that may result in a final pH above 6 since norepinephrine bitartrate is alkali labile.<sup>6</sup>

Visual inspection for color change may be inadequate to assess compatibility of admixtures. In one evaluation with aminophylline stored at 25°C, a color change was not noted until 48 hours had elapsed. However, no intact norepinephrine bitartrate was present in the admixture at 48 hours.<sup>527</sup>

#### Syringes

Norepinephrine bitartrate (Aguettant) 0.24 mg/mL in sodium chloride 0.9% was packaged in 50-mL polypropylene syringes (Becton Dickinson) and stored at 2 to 8°C with light protection.<sup>3508</sup> Solutions were physically stable with less than 10% loss in 30 days.<sup>3508</sup>

Norepinephrine bitartrate 0.5 and 1.16 mg/mL in dextrose 5% was packaged as 48 mL in 50-mL clear polypropylene and amber polypropylene syringes (Becton Dickinson) and stored at 20 to 25°C.<sup>3509</sup> Solutions both with and without light protection were physically stable with little to no loss of drug in 48 hours.<sup>3509</sup>

Noradrenaline (as the tartrate salt) (Aguettant) 6 mg/50 mL and 12 mg/50 mL in sodium chloride 0.9% in a 50-mL polypropylene syringe (BD) was physically stable for 48 hours at room temperature.<sup>3545</sup>

#### Filtration

Norepinephrine bitartrate 4 mg/L in dextrose 5% and sodium chloride 0.9% was filtered at a rate of 120 mL/hr for 6 hours through a 0.22-µm cellulose ester membrane filter (Ivex-2). No significant drug loss due to binding to the filter was noted.<sup>533</sup>

#### Central Venous Catheter

Norepinephrine bitartrate 0.1 mg/mL in dextrose 5% was found to be compatible with the ARROWg+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

<sup>n</sup> Salt not specified.

<sup>o</sup> Test performed using the formulation WITH edetate disodium.

## Octreotide Acetate

AHFS 68:29.04

### Products

Octreotide acetate injection is available in 1-mL ampuls containing 0.05 mg (50 mcg), 0.1 mg (100 mcg), and 0.5 mg (500 mcg) of octreotide and in 5-mL multiple-dose vials containing 0.2 mg (200 mcg) and 1 mg (1000 mcg) of octreotide in each mL.<sup>1(1/09)</sup>

The Sandostatin (Sandoz) products also contain in each mL lactic acid 3.4 mg, mannitol 45 mg, phenol 5 mg (vial only), and sodium bicarbonate to adjust pH in water for injection.<sup>1(1/09)</sup>

Octreotide acetate (Bedford) has a differing formulation. In addition to the octreotide acetate, the Bedford formulation in ampuls and multidose vials contains in each mL L-lactic acid 3 mg and sodium chloride 7 mg with sodium hydroxide for pH adjustment in water for injection. The multidose vials also contain phenol 5 mg/mL as a preservative.<sup>1(1/09)</sup>

### pH

From 3.9 to 4.5.<sup>1(1/09)</sup>

### Trade Name(s)

Sandostatin

### Administration

Octreotide acetate injection usually is administered by subcutaneous injection in the smallest volume that will deliver the dose. Subcutaneous injection sites should be rotated. Multiple subcutaneous injections at the same site within a short time should be avoided. Administration by intravenous injection over 3 minutes or by infusion over 15 to 30 minutes after further dilution with 50 to 200 mL of dextrose 5% or sodium chloride 0.9% also has been recommended.<sup>1(1/09)</sup> <sup>4</sup> NOTE: Do not confuse octreotide acetate injection with the injectable depot suspension product, which cannot be given by these routes of administration.<sup>1(1/09)</sup>

## Compatibility Information

### Solution Compatibility

#### Octreotide acetate

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Sodium chloride 0.9%	TR <sup>a</sup>	SZ	1.5 mg	Little octreotide loss over 48 hr at room temperature in ambient room light	1373	C
TNA #139 <sup>b</sup>	<sup>c</sup>	SZ	450 mcg	Physically compatible with no change in lipid particle size in 48 hr at 22°C under fluorescent light and 7 days at 4°C. Octreotide activity highly variable	1540	?
TPN #119, #120 <sup>b</sup>	<sup>a</sup>	SZ	1.5 mg	Little octreotide loss over 48 hr at room temperature in ambient room light	1373	C

<sup>a</sup> Tested in PVC containers.

<sup>b</sup> Refer to Appendix for the composition of parenteral nutrition solutions. TNA indicates a 3-in-1 admixture, and TPN indicates a 2-in-1 admixture.

<sup>c</sup> Tested in both glass and ethylene vinyl acetate (EVA) containers.

### Stability

Octreotide acetate injection is a clear solution. Ampuls and vials should be stored under refrigeration and protected from light. However, octreotide acetate injection can be stored at room temperature for up to 14 days when protected from light.<sup>1(1/09)</sup> <sup>4</sup>

The manufacturers state that octreotide acetate injection should not be added to total parenteral nutrition solutions because of the formation of a glycosyl octreotide conjugate that may decrease the product's efficacy,<sup>1(1/09)</sup> although the clinical value of this administration approach has been debated.<sup>2136</sup>

### Syringes

The stability of octreotide acetate injection (Sandoz) 0.2 mg/mL packaged as 1 mL in 3-mL polypropylene syringes sealed with tip caps (Becton Dickinson) was evaluated at 3 and 23°C both exposed to and protected from normal room light. No octreotide acetate loss was found in 29 days stored at 3°C protected from light, but about 7 to 9% loss occurred in 15 to 22 days exposed to light. At 23°C, the drug was less stable. Although results were variable, more than 10% loss occurred in about 2 weeks. Maximum storage of 1 week at 23°C, whether protected from light or not, was recommended.<sup>2020</sup>

In a similar study, the stability of octreotide acetate injection (Sandoz) 0.2 mg/mL was evaluated for 60 days stored at 5 and -20°C (light conditions unspecified). The undiluted octreotide acetate injection was packaged as 1 mL in 3-mL polypropylene syringes (Terumo) and sealed with a cap. A loss of about 6% at both storage conditions after 60 days was found.<sup>2021</sup>

### Sorption

The manufacturer indicates that octreotide, a peptide, has the potential for adsorption to plastic and, possibly, glass.<sup>1540</sup> However, the drug was not adsorbed to glass infusion bottles or a polyvinyl chloride (PVC) administration set at a concentration of 5 mcg/mL in sodium chloride 0.9%.<sup>1371</sup>

## Omadacycline Tosylate

AHFS 8:12.24.04

### Products

Omadacycline tosylate is available in single-dose vials as a cake of lyophilized powder containing the equivalent of 100 mg of omadacycline and 100 mg of sucrose in each vial.<sup>3435</sup> Each 100-mg vial should be reconstituted with 5 mL of sterile water for injection.<sup>3435</sup> Vials should be swirled gently and then left to stand until the cake has dissolved completely and any foam has dispersed; vials should not be shaken.<sup>3435</sup> The reconstituted solution should be visually inspected for particulate matter and discoloration prior to further dilution.<sup>3435</sup> If necessary, vials may be inverted and swirled gently to dissolve any remaining powder.<sup>3435</sup>

The appropriate dose of the reconstituted solution should be further diluted immediately (within 1 hr) to a volume of 100 mL with sodium chloride 0.9% or dextrose 5% to a final omadacycline concentration of 1 or 2 mg/mL.<sup>3435</sup> The diluted solution should be visually inspected for particulate matter and discoloration prior to administration.<sup>3435</sup>

### Equivalency

Omadacycline tosylate 131 mg is equivalent to 100 mg of omadacycline.<sup>3435</sup>

### Trade Name(s)

Nuzyra

### Administration

Omadacycline tosylate is administered by intravenous infusion through a dedicated intravenous line or through a Y-site after

reconstitution and further dilution; 100-mg doses should be infused over 30 minutes and 200-mg doses should be infused over 60 minutes.<sup>3435</sup> If a common infusion line is being used to administer other drugs in addition to omadacycline tosylate, the line should be flushed with sodium chloride 0.9% or dextrose 5% prior to and following infusion of omadacycline tosylate.<sup>3435</sup> Omadacycline tosylate must not be administered through the same intravenous line with any solution containing multivalent cations (e.g., calcium, magnesium).<sup>3435</sup>

### Stability

Omadacycline tosylate is a yellow to dark orange powder that forms a yellow to dark orange solution upon reconstitution.<sup>3435</sup> Intact vials should be stored at controlled room temperature.<sup>3435</sup> The reconstituted solution of omadacycline should be diluted immediately (within 1 hour).<sup>3435</sup> The diluted solution in sodium chloride 0.9% or dextrose 5% should be used within 12 hours if stored at room temperature (not exceeding 25°C) or within 48 hours if stored at 2 to 8°C.<sup>3435</sup> If the diluted solution has been stored under refrigeration, it should be removed from the refrigerator and kept at room temperature in an upright (vertical) position for 60 minutes prior to use.<sup>3435</sup>

### Freezing Solutions

The manufacturer states that diluted solutions of omadacycline should not be frozen.<sup>3435</sup>

## Compatibility Information

Sodium chloride 0.9%		PTK	1 and 2 g	Use within 12 hr if stored at room temperature up to 25°C or 48 hr if stored at 2 to 8°C	3435	C

## Additional Compatibility Information

### Infusion Solutions

Omadacycline tosylate must not be administered through the same intravenous line with any solution containing multivalent cations (e.g., calcium, magnesium).<sup>3435</sup>

## Omeprazole Sodium

AHFS 56:28.36

### Products

Omeprazole *for infusion* is available as a powder in vials containing 40 mg of the drug as the sodium salt<sup>3408 3409</sup> or 40 mg of the drug as the base.<sup>3410</sup> Each vial of the drug also contains disodium edetate and sodium hydroxide for pH adjustment.<sup>3408 3409 3410</sup> Each 40-mg vial of omeprazole should be reconstituted with 5 mL of solution withdrawn from a 100-mL infusion bag or bottle of sodium chloride 0.9% or dextrose 5% and then mixed thoroughly until all of the powder has dissolved.<sup>3408 3409 3410</sup> The reconstituted solution should then be transferred back into the same 100-mL infusion bag or bottle from which the solution used for reconstitution was withdrawn.<sup>3408 3409 3410</sup>

Omeprazole *for injection* is available as a powder in vials containing 40 mg of the drug as the sodium salt with an accompanying ampul containing 10 mL of solvent.<sup>3411</sup> Each vial of the drug also contains sodium hydroxide.<sup>3411</sup> The solvent contains citric acid monohydrate and polyethylene glycol 400 in water for injection.<sup>3411</sup> Each 40-mg vial of omeprazole should be reconstituted only with 10 mL of the provided solvent; no other solvents should be used.<sup>3411</sup>

### Equivalency

Omeprazole sodium 42.6 mg is equivalent to 40 mg of omeprazole.<sup>3408</sup>

### pH

The pH of omeprazole (Azevedos) 0.4-mg/mL solution (reconstituted from omeprazole sodium) in dextrose 5% and sodium chloride 0.9% ranges from 8.9 to 9.5 and from 9.3 to 10.3, respectively.<sup>3408</sup>

The pH of omeprazole (Sandoz) 0.4-mg/mL solution (reconstituted from omeprazole sodium) in dextrose 5% or sodium chloride 0.9% ranges from 9 to 10.5.<sup>3409</sup>

The pH of a reconstituted solution of 40 mg of omeprazole (Sandoz) (reconstituted from omeprazole sodium) prepared with 10 mL of accompanying solvent is about 8.6.<sup>3411</sup>

### Osmolality

The osmolality of omeprazole (Sandoz) 0.4-mg/mL solution (reconstituted from omeprazole sodium) in dextrose 5% or sodium chloride 0.9% is 297 or 282 mOsm/kg, respectively.<sup>3409</sup>

## Compatibility Information

### Solution Compatibility

#### Omeprazole sodium

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 5%	BA	PH	400 mg	Physically compatible. 10% loss occurs in 2.5 days at 22°C in light	2696	C
Dextrose 5%		SZ	400 mg	Stable for 6 hr below 25°C or 24 hr at 2 to 8°C	3409	C

### Administration

Omeprazole is administered by intravenous infusion<sup>3408 3409 3410</sup> or by intravenous injection,<sup>3411</sup> depending upon the product used.

After omeprazole *for infusion* is reconstituted and diluted to 100 mL with sodium chloride 0.9% or dextrose 5%, it should be administered as a 20- to 30-minute intravenous infusion.<sup>3408 3409 3410</sup>

After omeprazole *for injection* is reconstituted with the accompanying solvent, it should be administered as a slow intravenous injection over at least 2.5 minutes at a maximum rate of 4 mL/min.<sup>3411</sup>

### Stability

Intact containers of omeprazole *for infusion* and omeprazole *for injection* (and accompanying solvent) generally should be stored at temperatures not exceeding 25°C in the outer carton to protect from light.<sup>3408 3409 3410 3411</sup>

Stability of omeprazole solutions varies depending upon which product is used; specific product labeling should be consulted.<sup>3408 3409 3410 3411</sup>

When stored at temperatures that do not exceed 25°C, omeprazole solutions *for infusion* are reportedly stable for 12 hours when prepared with sodium chloride 0.9%,<sup>3408 3409</sup> for 6 hours when prepared with dextrose 5%,<sup>3408 3409</sup> or for 6 hours in either solution;<sup>3410</sup> when stored at 2 to 8°C, one product has been reported as stable for 24 hours in either solution.<sup>3409</sup>

Omeprazole *for injection* reconstituted with the accompanying solvent is stable for up to 4 hours when stored at temperatures below 25°C.<sup>3411</sup>

### Light Effects

Intact containers of omeprazole, omeprazole sodium, and solvent, when provided, should be stored in their outer carton to protect from light.<sup>3408 3409 3410 3411</sup> At least one manufacturer states that vials may be exposed to normal indoor light outside of the box for up to 24 hours.<sup>3408</sup>

Reconstituted omeprazole (AstraZeneca) has been reported to develop an unacceptable discoloration indicating decomposition within 6 hours at room temperature when exposed to light.<sup>2507</sup>

# Ondansetron Hydrochloride

**AHFS 56:22.20**

## Products

Ondansetron hydrochloride is available in 20-mL multiple-dose vials and 2-mL single-dose vials.<sup>2836 2837</sup> Each mL of solution in multiple-dose vials contains ondansetron (as the hydrochloride dihydrate) 2 mg with sodium chloride 8.3 mg, citric acid monohydrate 0.5 mg, sodium citrate dihydrate 0.25 mg, methylparaben 1.2 mg, and propylparaben 0.15 mg in water for injection.<sup>2836 2837</sup> Each mL of solution in single-dose vials contains ondansetron (as the hydrochloride dihydrate) 2 mg with sodium chloride 9 mg, citric acid monohydrate 0.5 mg, and sodium citrate dihydrate 0.25 mg in water for injection.<sup>2836</sup>

## pH

From 3.3 to 4.<sup>2836</sup>

## Trade Name(s)

Zofran

## Administration

Ondansetron hydrochloride is administered by intravenous infusion over 15 minutes after further dilution with 50 mL of sodium chloride 0.9% or dextrose 5%.<sup>2836 2837</sup> By intravenous injection, it is administered undiluted over at least 30 seconds and preferably over 2 to 5 minutes.<sup>2836 2837</sup>

Ondansetron hydrochloride also has been administered intramuscularly *without* dilution.<sup>2836 2837</sup>

## Stability

Ondansetron hydrochloride is a clear, colorless solution.<sup>2836 2837</sup> It should be stored at 2 to 30°C and protected from light.<sup>2836 2837</sup> Although ondansetron hydrochloride is unstable under intense light, it is stable for about 1 month in daylight with added fluorescent light.<sup>1366</sup> Ondansetron occasionally may precipitate at the stopper/vial interface in vials that are stored upright; the potency and safety of ondansetron are not affected.<sup>2836 2837</sup> If a precipitate is observed, the drug may be resolubilized by vigorously shaking the vial.<sup>2836 2837</sup>

Ondansetron hydrochloride (Glaxo) 0.03 and 0.3 mg/mL in dextrose 5% or sodium chloride 0.9% was stable when frozen at -20°C, exhibiting a 10% or less loss in 3 months.<sup>1642</sup>

## pH Effects

The natural pH of ondansetron hydrochloride solutions is about 4.5 to 4.6.<sup>1366 1367</sup> The pH of commercially available ondansetron

solution has been adjusted with citric acid monohydrate and sodium citrate dihydrate to the range of 3.3 to 4.<sup>2836 2837</sup> If the pH is increased, a precipitate of ondansetron free base has been reported to develop at pH 5.7<sup>1366</sup> and pH 7.<sup>1513</sup> Redissolution of the ondansetron precipitate occurs at pH 6.2 when titrated with hydrochloric acid.<sup>1513</sup> Precipitation by combination with alkaline drugs has been observed.<sup>1365 1513</sup>

## Syringes

The stability of ondansetron hydrochloride undiluted at 2 mg/mL and diluted in dextrose 5% and sodium chloride 0.9% at 1, 0.5, and 0.25 mg/mL packaged in polypropylene syringes was reported. Representative syringes were stored at 24°C for 48 hours, 4°C for 14 days, and frozen at -20°C for 90 days. Visually, the solutions exhibited no precipitate or color or clarity changes. Ondansetron hydrochloride concentrations in all samples remained above 90%; most samples were above 95%. Sequentially storing sample syringes for 90 days at -20°C followed by 14 days at 4°C followed by 48 hours at 24°C did not alter the stability.<sup>2056</sup>

When diluted with compatible infusion solutions, ondansetron hydrochloride is stable for up to 7 days at room temperature or under refrigeration in Plastipak syringes with syringe caps.<sup>1366</sup>

## Filtration

Ondansetron hydrochloride (Glaxo) 0.03 and 0.2 mg/mL (30 and 200 mcg/mL) in sodium chloride 0.9% was delivered over 15 minutes through 5 different 0.2- $\mu$ m inline filters: Continu-Flo Solution Set (Baxter, 2C5561S), Filtered Extension Sets (Burr, PFE-2007 and FE-2024), Universal Primary infusion set (IVAC, 52023), and Ivex-HP Filterset-SL (Abbott, 4524). Little or no ondansetron loss was found.<sup>1678</sup>

## Central Venous Catheter

Ondansetron hydrochloride (Glaxo Wellcome) 0.2 mg/mL in dextrose 5% was found to be compatible with the ARROW-g+ard Blue Plus (Arrow International) chlorhexidine-bearing triple-lumen central catheter. Essentially complete delivery of the drug was found with little or no drug loss occurring. Furthermore, chlorhexidine delivered from the catheter remained at trace amounts with no substantial increase due to the delivery of the drug through the catheter.<sup>2335</sup>

## Oritavancin Diphosphate

AHFS 8:12.28.16

### Products

Oritavancin is available as a lyophilized powder in single-use (unpreserved) vials containing oritavancin diphosphate equivalent to oritavancin 400 mg as the free base and mannitol.<sup>2927</sup> Phosphoric acid has been added to adjust the pH.<sup>2927</sup>

Each vial should be reconstituted with 40 mL of sterile water for injection to yield a solution containing oritavancin 10 mg/mL.<sup>2927</sup> To avoid foaming, each vial should be gently swirled until the contents are completely dissolved.<sup>2927</sup> Vials contain a calculated excess (equivalent to a total of 405 mg of oritavancin) so that when reconstituted as directed, 400 mg of the drug can be withdrawn from the vial.<sup>2927</sup>

To prepare a 1.2-g dose, 120 mL should be removed from a 1-L intravenous bag of dextrose 5% and discarded.<sup>2927</sup> From each of 3 reconstituted vials of oritavancin, 40 mL should be withdrawn and transferred to the dextrose 5% bag to bring the total bag volume to 1 L, yielding a final concentration of oritavancin 1.2 mg/mL.<sup>2927</sup>

### Equivalency

Oritavancin diphosphate 449 mg is equivalent to 405 mg of oritavancin free base.<sup>2927</sup>

### pH

From 3.1 to 4.3.<sup>2927</sup>

### Trade Name(s)

Orbactiv

## Compatibility Information

### Solution Compatibility

#### Oritavancin diphosphate

Test Soln Name	Mfr	Mfr	Conc/L or %	Remarks	Ref	C/I
Dextrose 5%		MEL	1.2 g	Complete administration within 6 hr after reconstitution and dilution if stored at room temperature or 12 hr if stored at 2 to 8°C	2927	C
Sodium chloride 0.9%		MEL		Stated to be incompatible	2927	I

### Y-Site Injection Compatibility (1:1 Mixture)

#### Oritavancin diphosphate

Test Drug	Mfr	Conc	Mfr	Conc	Remarks	Ref	C/I
Aminophylline	AMR	1 mg/mL <sup>a</sup>	TAR	0.8, 1.2, and 2 mg/mL <sup>a</sup>	Haze or precipitate forms immediately	2928	I
Amphotericin B	XGN	0.1 mg/mL <sup>a</sup>	TAR	0.8, 1.2, and 2 mg/mL <sup>a</sup>	Slight haze forms immediately	2928	I
Aztreonam	BMS	20 mg/mL <sup>a</sup>	TAR	0.8, 1.2, and 2 mg/mL <sup>a</sup>	Precipitate forms immediately	2928	I
Bumetanide	HOS	0.1 mg/mL <sup>a</sup>	TAR	0.8, 1.2, and 2 mg/mL <sup>a</sup>	Haze forms immediately with precipitate after 30 min	2928	I

### Administration

Oritavancin is administered by intravenous infusion over 3 hours after dilution only in dextrose 5%.<sup>2927</sup> If a common infusion line is being used to administer other drugs in addition to oritavancin, the line should be flushed with dextrose 5% prior to and following infusion of oritavancin.<sup>2927</sup> Administration of the diluted drug over 3 hours is intended to minimize the risk of infusion-related reactions; however, interruption of the infusion or reduction in the rate of infusion may be necessary if such reactions occur.<sup>2927</sup>

### Stability

Oritavancin diphosphate is a white to off-white powder that forms a clear, colorless to pale yellow solution when reconstituted with sterile water for injection and when further diluted in dextrose 5%.<sup>2927</sup> Intact vials of oritavancin diphosphate should be stored at controlled room temperature.<sup>2927</sup>

The manufacturer states that the diluted solution should be used within 6 hours of preparation when stored at room temperature or within 12 hours when refrigerated at 2 to 8°C.<sup>2927</sup> The total time for storage (the reconstituted drug in the vial and the diluted solution in the infusion bag) and the infusion time together should not exceed 6 hours if stored at room temperature or 12 hours if stored under refrigeration.<sup>2927</sup>

### pH Effects

Oritavancin may be incompatible with drugs formulated at a basic or neutral pH.<sup>2927</sup>

## Oxacillin Sodium

AHFS 8:12.16.12

### Products

Oxacillin sodium is available in vials containing the equivalent of oxacillin 1 and 2 g. A 10-g hospital bulk package also is available. The products contain dibasic sodium phosphate 20 mg/g of drug.<sup>4</sup>

For intramuscular use, reconstitute the 1-g vials with 5.7 mL and the 2-g vials with 11.5 mL of sterile water for injection or sodium chloride 0.45 or 0.9% and shake until a clear solution is obtained. A 250-mg/1.5 mL (167-mg/mL) solution results.<sup>4</sup>

For direct intravenous injection, reconstitute the 1- or 2-g vials with 10 or 20 mL, respectively, of sterile water for injection, sodium chloride 0.45%, or sodium chloride 0.9% and shake until a clear solution is obtained to yield a 100-mg/mL concentration.<sup>4</sup>

The 10-g hospital bulk package is reconstituted with 93 mL of sterile water for injection to yield a 100-mg/mL solution.<sup>4</sup>

Frozen premixed solutions of oxacillin 1 g/50 mL in dextrose 3% and 2 g/50 mL in dextrose 0.6% are also available. The solutions also contain sodium citrate buffer and hydrochloric acid and/or sodium hydroxide to adjust the pH.<sup>1(2/07) 4</sup>

### pH

From 6 to 8.5.<sup>17</sup> At 10 g/L in dextrose 5%, the pH has been variously reported as 7.4<sup>149</sup> and 7.94.<sup>153</sup> At this concentration in sodium chloride 0.9%, the pH has been reported as 7.73.<sup>153</sup>

### Osmolality

The osmolality of oxacillin sodium 250 mg/1.5 mL in sterile water for injection was 596 mOsm/kg by freezing-point depression and 657 mOsm/kg by vapor pressure.<sup>1071</sup>
